The 1 per cent sodium ricinoleate possesses some bacteriostatic activity, but due care must be exercised against contamination of the vaccine when administered.

Since we have never seen the slightest ill effects, aside from mild local reactions at the sites of injection in monkeys or the twenty-seven human beings including two of us (J A K and A M R) who have taken it, we lost all fear of infection from its administration and are sure that it is perfectly safe. Unfortunately the monkey serum neutralization test is the only one available at present for the detection of susceptibility,¹² since skin tests,¹³ colloidal gold, complement fixation and precipitation tests¹⁴ have proved inadequate, but the majority of children under 10 years of age are devoid of antiviral antibody and probably susceptible, and since Aycock has shown that there is an important hereditary factor in susceptibility it would appear particularly important to vaccinate all children in those families in which the disease has appeared.

Not only is it quite likely that the remote passage virus employed has lost some if not all infectivity for human beings, but it is certainly attenuated to some extent by the sodium ricinoleate employed. Furthermore subcutaneous injections appear to add another very important factor of added safety, as it represents a portal of entry in which virulent virus itself has a

very low rate of infectivity for monkeys. In addition the injection of such a small first dose as from 0.25 to 0.5 cc to children and adults and waiting at least a week before the second dose is given adds another important factor of safety since it appears that antibody response is quite prompt. For these reasons we do not hesitate recommending the vaccine especially during epidemics, and among the first children to receive it were the two sons of the senior author the younger of whom was without any antibody at all in his serum before the first dose of 0.5 cc was given.

SUMMARY

1 Twenty-five children varying in age from 8 months to 15 years have been given from one to three injections of poliomyelitis vaccine at the request or with the consent of parents.

2 Fifteen of these children were without antibody in serum neutralization tests before immunization and eleven or 75 per cent, showed large amounts of antibody in the blood one week after the last dose of vaccine.

3 Ten of the children showed the presence of antiviral antibody in the blood before immunization, but all have shown a considerable increase of this antibody after vaccination so that antibody production occurred in twenty-one or 84 per cent of the group of twenty-five children.

4 None of the twenty-five children have shown the slightest ill effects from the vaccine.

5 Mild local reactions were produced at the sites of subcutaneous injection, with occasional slight elevation of temperature and slight leukocytosis subsiding within forty-eight hours.

6 The dosage for children from 1 to 3 years of age has been 0.25, 0.5 and 0.5 cc at weekly intervals, for children from 4 to 10 years 0.5, 0.5 and 1 cc, for children from 11 to 15 years 0.5, 1 and 1 or 2 cc. For adults the dosage recommended is 0.5, 1 and 2 cc.

7 The vaccine is prepared of spinal cord only, as brain contains too small amounts of virus. But the spinal cord of a single monkey will furnish about 150 cc of vaccine which is sufficient for the immunization of from forty to seventy-five children, depending on age and dosage.

8 It is likely that the maximum antibody response may be obtained by giving the injection every ten days instead of weekly.

9 Antibody production, however, appears to be fairly rapid as three susceptible children developed antibody in the blood within four days after the first injection of vaccine and one monkey was found completely and a second partially immune seventy-two hours after the subcutaneous injection of 0.5 cc of vaccine per animal on intracerebral inoculations of large amounts of virus.

10 The vaccine does not appear to produce a demonstrable "negative phase" of increased susceptibility after injection.

11 The vaccine is a 4 per cent suspension of spinal cords of monkeys developing poliomyelitis after intracerebral inoculation with a remote passage strain of virus in a 1 per cent sterile solution of sodium ricinoleate prepared as previously described. The virus is attenuated and the vaccine regarded as entirely safe for the immunization of human beings not only because prepared of remote passage virus which probably has

lost in infectivity for human beings but likewise because of attenuation by sodium ricinoleate, the route of administration and the injection of a small first dose.

12 The amount of antibody produced by immunizations is comparable to that found in the blood in natural immunity and is believed to be sufficient for affording protection against acute anterior poliomyelitis.

13 The antibody present in the serums of vaccinated children has successfully neutralized human virus from the 1934 California epidemic.

14 The duration of the immunity following vaccination is unknown but has lasted for more than two years in vaccinated monkeys.

15 It is believed that the vaccine is now ready for vaccination of human beings and especially children against poliomyelitis and particularly during epidemics.

Clinical Notes, Suggestions and New Instruments

LYMPHOBLASTOMA WITH PARAPLEGIA AND PROLONGED IRRADIATION

L. F. WHEATLEY, M.D., NEW HAVEN, CONN.

This case of lymphoblastoma (Hodgkin's type) is reported because of a number of points of unusual interest: certain neurologic and skin manifestations, its response to radiation therapy over a considerable period of time, and the changes found at autopsy.

The patient first came under my observation at 12 years of age with a negative family history and negative past history until 9 years of age, when she had mumps in the left parotid gland. A year later there was an enlarged cervical gland on the same side which was removed surgically. A year later there was a recurrence, which was again operated on. At this time it was considered tuberculous and the patient was referred to a tuberculosis sanatorium, where routine examination of the chest disclosed a large superior mediastinal growth corresponding to Wessler's group I—expanding mediastinal tumor. A recurring cervical gland enlargement was excised at this time and microscopic examination showed it to be a slow growing lymphoblastoma of the Hodgkin's type, which thus identified the mediastinal growth. At this time then three years after her first glandular involvement she was referred to me for radiation therapy. She was given heavily filtered high voltage (180 kilovolts) radiation over the upper mediastinum, anteriorly and posteriorly approximately a 40 per cent depth dose into the tumor mass, and moderate voltage (125 kilovolts) with a filter of 3 mm of aluminum over the cervical gland. The mediastinal growth entirely disappeared following this treatment.

She remained well for five years, when gastro-intestinal symptoms and a slight rise of temperature occurred, which I thought due to probable mesenteric lymphoid involvement. Chest examination showed some recurrence of the mediastinal tumor mass, which promptly receded again under radiation therapy.

A year later she developed partial paraplegia, exhibiting great difficulty in walking and numbness from the shoulders down. I considered this evidence of the extension of the mediastinal growth into the spinal cord and pressure on the nerve exits from the vertebral bodies. Roentgen examination showed no erosion of the vertebral bodies. Heavy (200 kilovolts) irradiation was again done over the upper dorsal spine, 860 roentgens being administered through each of two oblique portals within a week. Three months later she reported herself able to swim and to walk a mile with the aid of a cane, and her numbness was nearly gone. Six months after the onset she was apparently in a normal condition again. During this time she had two cycles of therapy similar to the one described. She remained well for nearly a year longer, when she again returned with aggravation of all the symptoms. At this time

she also had an aggravated case of herpes zoster, completely encircling the body on the level with the twelfth dorsal vertebra, which left deep scars. Radiation directed over the spine again relieved the gastro intestinal symptoms, but the condition gradually grew worse. A laminectomy was considered to relieve pressure on the cord, but she was in very poor condition and I did not feel justified in taking the risk. Complete paralysis and anesthesia of both extremities, paralytic ileus, and urinary and fecal incontinence with ascending urinary infection developed, and the patient died.

AUTOPSY

When the chest cavity was opened the left lung was seen to be adherent with numerous adhesions to the entire lateral wall and to the diaphragm, with more dense adhesions about the apex. The entire chest contents, including the mediastinum and heart, were removed *en masse*. The heart was small and the pericardium was adherent to the epicardium throughout the thin easily separated fibrous adhesion, which left the epicardium smooth but remained as tags on the pericardium. There were numerous various sized lymph nodes scattered all along the spinal column retroperitoneally, and one large calcified lymph node in the mesentery of the small intestine. The spinal cord was exposed and completely removed from the fourth lumbar vertebra to the brain. Beginning at the level of the sixth dorsal vertebra and extending to the last cervical vertebra was an extradural tumor mass adherent to the dura and extending out between the ribs on the right side most markedly in the third interspace, but also in the second and fourth interspaces. This mass was entirely extradural and undoubtedly caused pressure on the cord. Opening of the dura, however, revealed no internal involvement whatever, and grossly the cord appeared perfectly normal. The tissue extending between the third and fourth ribs was excised and extended through to the pleural cavity, with no apparent bulging or involvement of the pleura itself. A single lymph node in the right neck was removed which on gross examination showed hemorrhagic mottlings.

Microscopic examination of sections of the node removed from the neck showed a cellular structure with large areas of necrosis. The cells were of a size suggesting those of the germinal centers of a lymph node. On occasion larger multinucleated cells were seen also in places there was some fibrous tissue and a few eosinophils were present. The normal architecture of the lymph nodes had disappeared. A retroperitoneal lymph node was quite similar but gave the impression of a more rapidly growing structure. An occasional dividing nucleus was seen. The extradural growth from the spinal canal and the extension out from that showed a similar picture as regards the type of cell present, but there was more fibrous tissue here than was seen of the lymph node described.

In my opinion the picture in this tissue and of the lymph node is to be explained as a chronic lymphoblastoma. Sections from the scar tissue in each apex of the lung showed compact fibrous tissue such as might have resulted from an old tuberculous process though no tubercles were present to make such a diagnosis definite. The spinal cord showed no evident degeneration.

COMMENT

Paraplegia occurring in the course of Hodgkin's disease is a relatively well known condition although few autopsy records have been reported. The response of such cases to irradiation are less well known or at least less frequently reported. It is of interest to note the initial response to irradiation which held it in check for nearly a year in this case. The mediastinal mass and the extension into the spinal canal had been reduced to fibrous tissue and it was the pressure of this mass confined within an elastic bony chamber that produced this paraplegia. It is fair to presume that if the patient had been in any condition to withstand a laminectomy she might have survived for a considerable period longer.

In a review of the literature, Paullen¹ reports four cases of lymphogranuloma of the central nervous system, with extension by the way of the intervertebral foramen and destruction of the vertebral bodies with discrete growth in the epidural

tissue of the spinal cord. There was temporary response to radiation treatment.

Parkes Weber² reports that there are very few definite cases with autopsy confirmation on record and but few with a history of improvement after high voltage radiation therapy.

Johnston³ describes two types of spinal involvement (a) degeneration of the cord due to anemia with resulting interference of the blood supply, and (b) pressure atrophy due to perineural infiltration. He states that most cases show compression myelitis from crushing of the bony canal or massive infiltration of the cord by granulomatous tissue.

Weil⁴ reports forty-three cases with spinal cord involvement in which 85 per cent showed this as due to granulomatous tissue, in 80 per cent the thoracic segments were involved in 16 per cent the cervical, and in 4 per cent the lumbar. There was no prolongation of life because of roentgen treatment, although he advocated early irradiation and laminectomy.

Cooper⁵ reported a case proved at autopsy of direct extension of this lymphogranulomatous tissue from an extradural tumor, with extensions by the way of the nerve roots to the subdural space.

In the case here reported, it was found at autopsy that lymphogranulomatous tissue reached the vertebral canal by direct extension from the mediastinal tumor mass by way of the intervertebral foramen and that there was no actual destruction of the cord but the extension into the subdural space produced symptoms by compression only.

The occurrence of herpes zoster has been reported by Craven and Haagensen⁶ as the expression of the involvement of the nervous system by granulomatous tissue, and they conclude that herpes zoster was caused by the new growth surrounding and compressing the ganglions corresponding to the peripheral areas involved. This conclusion was based on the autopsy.

Keichline⁷ states that in every case this is a trophic expression of inflammation corresponding to the ganglion of the posterior roots either spinal or cranial.

The blood Wassermann was 4+ and precipitation test (Kahn) was 3+, confirmed on several examinations. The father's and mother's blood were both negative on repeated examinations. The occurrence of repeated positive Wassermann reactions is of considerable interest. Moore, in his textbook of Modern Treatment of Syphilis, acknowledges a non-specific positive occurring in certain conditions such as malignant cachexias, glandular tuberculosis and yaws. The apparent close relation between Hodgkin's disease and tuberculosis suggests that Hodgkin's disease might possibly be included in this list. On the other hand other syphilologists feel that there is a congenital syphilis in these cases and that repeated negatives in the parents indicate a spontaneous cure. In the present case there was a history of the father having been treated with mercurial inunctions when a youth, but there is no further history bearing on this point. The autopsy was entirely negative for any evidence of syphilis and there had never been any clinical evidence suggestive of this condition.

SUMMARY

A case of lymphoblastoma was observed over a period of ten years and kept under almost complete control by roentgen therapy up to three months before the patient's death. The recurring mediastinal growth was held in check and finally reduced to a small mass of scar tissue. The developing paraplegia also responded to irradiation and almost complete relief of symptoms for a period of one year and I believe might further have been controlled had the patient's condition justified a laminectomy. The patient developed an aggravated case of herpes zoster and showed a persistent Wassermann reaction without clinical or autopsy confirmation.

AN OBSTETRIC RING FOR ARTIFICIAL PUNCTURE
OF THE MEMBRANES

IRVING F. STEIN, M.D., CHICAGO

Artificial puncture of the membranes is the simplest of obstetric operations. When one observes the awkwardness with which the operation is performed by inexperienced physicians and the amount of unnecessary trauma sometimes inflicted in attempting to rupture the membranes, the need for a simple, effective and harmless instrument becomes obvious.

The ring that I have devised is made of malleable metal so that it can be fitted to the gloved forefinger just behind the first joint. A rigid, notched projection extends along the dor-

Fig. 1—Obstetric rings for fingers of right or left hand

sum of the first phalanx with the point directed to the inner aspect of the fingernail. When the finger is introduced into the vagina, the projection lies flat against the gloved finger, so that no trauma is inflicted on the mucous membrane of the vagina or on the cervix. Examination of the cervix and of the presenting parts may be made by means of the palmar surface or the tip of the finger and when puncture of the membranes is indicated the finger is bent slightly, releasing the notched projection. The puncture is readily accomplished by rotating the finger medially. The finger is again straightened and further examination of the presenting parts may be made to verify the position and to feel for a prolapsed cord, an extremity and so on. Furthermore, the finger is in a favorable position to control the rate of escape of the liquor.

The disadvantages of previous methods employed for artificial rupture of the membranes are as follows: 1. The notched finger-nail described by Edgar appropriated from the ancient midwife, is obviously antiquated by the universal use of rubber gloves and is no longer approved by obstetricians. 2. The notched thumb requires a separate introduction of the finger into the vagina after the diagnosis has been made and a decision reached that the membranes shall be ruptured. The touch

Fig. 2—A palpation of bag of waters with palmar surface of finger. B method of rupturing bag of waters with author's instrument by bending and rotating finger.

surface of the finger is obliterated by the thumb. 3. Blunt or sharp forceps, scissors or crochet hooks require a separate insertion into the vagina and also carry the danger of trauma to the cervix and to the presenting part of the fetus.

The obstetric ring here described may be worn for every vaginal examination whether or not it is needed. It is light in weight and does not interfere with the vaginal touch or cause trauma. Thus the necessity of a second insertion of the finger or of an instrument is obviated if a decision is made

to puncture the bag of forewaters. The obstetric ring has been tested in the Michael Reese Hospital maternity for several months, during which time it has been employed by members of the attending and house staffs with entire satisfaction. It may be obtained for use on either the right or the left hand according to the habit of the individual physician.¹

DEVICE FOR PROTECTION OF THE TEETH DURING
BRONCHOSCOPY AND ESOPHAGOSCOPY

SIDNEY ISRAEL, M.D., HOUSTON, TEXAS

Protection of the upper teeth is one of the important factors in the technique to be observed during a bronchoscopic or esophagoscopic examination. There have been numerous occurrences of injury to the upper teeth, regardless of what instrument or method has been employed.

Unless the teeth have been properly protected, patients frequently complain of sensitiveness or tenderness of the teeth, particularly on the edges, lasting for several days after a bronchoscopic or esophagoscopic examination, as a result of the pressure of the metal tube, which rests on the edges of the teeth.

Heretofore to protect the upper teeth from injury by the bronchoscopic or esophagoscopic tube it has been the accepted

Rubber protector in place over upper teeth ready for introduction of the bronchoscopic or esophagoscopic tube.

custom to use the examiner's thumb or a pad of gauze or cotton. Neither of these measures is completely satisfactory. When the thumb of one hand is used, that hand is eliminated so far as the execution of any operative manipulation is concerned. When gauze or cotton is employed to protect the upper teeth the bulk either obstructs the mouth or is easily displaced.

For the purpose of protecting the upper teeth and safeguarding them from any injury or discomfort following an endoscopic examination, flexible rubber tooth guards were devised to cover the upper teeth. The endoscopic tube rests on the rubber guards over the teeth, rendering both hands free for the performance of any necessary operative procedure. These rubber protectors have accomplished the purpose for which they were designed and have proved very successful.

In order to arrive at standard or universal sizes, the mouths of a number of children and adults, as well as edentulous individuals, were examined. From these three classifications an average was obtained, and from these averages molds were made which represent standard sizes in the three classifications: (1) child, (2) adult and (3) edentulous. The three sizes of tooth guards, as the result of their flexibility, will conform to fit all mouths belonging in their respective class. They offer no obstruction or curtailment to instrumentation, remain in

place, and completely protect the teeth from injury. They can be easily cleaned or sterilized and are quickly applied or removed.

Aside from the protection offered through this medium of safeguarding the patient's teeth, it does much to eliminate any medicolegal controversy that may arise.

These tooth protectors are available through the Electro-Surgical Instrument Company of Rochester, N. Y.

Special Articles

GLANDULAR PHYSIOLOGY AND THERAPY INTRODUCTION

MORRIS FISHBEIN, M.D.
CHICAGO

In 1924 a series of articles—published in book form the following year and revised in 1927—was prepared under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association with the general title "Glandular Therapy." In a brief introduction to that series Dr. Frank Billings emphasized certain significant factors in relationship to our knowledge of the glands which at that time many endocrinologists considered as established but which to some physiologists and clinicians were not quite acceptable. The points to which he referred concerned the alleged reciprocal action of the glands of internal secretion, i. e., the idea that the glands represent an interlocking chain of structures correlated in their activities through hormones carried in the blood stream. This led to the view that the entire functioning of the body might be stimulated, retarded or perverted by hyperfunction, hypofunction or alleged dysfunction of the ductless glands. It seems reasonable to believe today that the endocrinologists have established this view. In 1927, when the revised edition of "Glandular Therapy" was published, evidence was still fragmentary. Today it is more elaborate but, of course, only a beginning has really been made in our knowledge of this exceedingly complex and fascinating field.

One of the reasons why the Council on Pharmacy and Chemistry took up the subject specifically in 1924 was the tremendous abuse already evident in the use of preparations of glandular materials promoted by pharmaceutical manufacturers who were willing to exploit such preparations on slight evidence. Notwithstanding the fact that evidence was already available at that time to indicate that most glandular materials could not become effective in the human body when taken by mouth, manufacturers offered tablets, powders and solutions to be taken orally, representing every tissue in the body that might even remotely be assumed to elaborate something in the nature of an internal secretion. The tonsil, the kidney, the spleen and the heart as well as the tissue of the brain were included in such mixtures. One manufacturer even went so far as to prepare a series of revolving wheels on which

were indicated various symptoms and a long series of numbered glandular preparations, the suggestion being that a summation of the symptoms would lead invariably to a glandular preparation of a certain number. Such obvious charlatanism could not long survive, particularly in the face of exact knowledge, which began to be accumulated. True, there are still some manufacturers who exploit preparations without scientific basis and with equally mysterious methods, but the majority of the medical profession seem to realize the folly of such therapeutics.

In 1927 there was but little in glandular therapy actually established. The entire volume made a book of some ninety-eight pages. There was evidence as to the usefulness of epinephrine and of the extract of the posterior pituitary. There was some usefulness indicated for thyroxine, thyroid gland tissue, insulin and parathyroid material, but beyond these there was little indeed that could be considered worth while. A comparison of that series of articles with the thirty contributions listed below as the constituents of the present series will indicate how interesting a road has been traveled in the intervening period. The concluding chapters of the book issued in 1927 dealt with the ovary and the mammary gland. The conclusion was then reached that ovarian therapy was wholly experimental and that there seemed to be little established, yet laboratory investigators indicated certain definite possibilities for the future. Mammary gland preparations were rejected entirely. In the present series of articles great emphasis is placed on the urinary, pituitary and placental gonadotropic factors. This pituitary-gonad relationship has led to conceptions of remarkable significance for clinical medicine.

Since 1927 the pituitary gland has been discovered to be a veritable storehouse of hormones. In addition to the growth hormone discussed by Evans and the gonadotropic principles considered by P. E. Smith, Collip speaks of diabetogenic, thyrotropic, adrenotropic and parathyrotropic factors. Riddle discusses the lactogenic factor, and Zondek the chromatophorotropic principle. The corpus luteum still constitutes a field for hopeful study rather than for any established therapeutic agent. Particularly significant from the discoveries of recent years have been those related to the estrogenic and gonadotropic substances and the application of such studies to the diagnosis of pregnancy. These, together with the work on the cortex of the adrenal, the thymus, the parathyroid and the testis, represent new phases of endocrinology that were hardly mentioned in the previous series.

The scope of research is today exceedingly broad. Hardly a month passes without an announcement of significance. Indeed, the progress is so rapid that it is hardly likely that another seven years will pass before a new edition, including many new facts and suggestions, will be required. Since it is of the greatest importance that clinicians be aware of what is established and what is still theoretical in this important field, the Council on Pharmacy and Chemistry has rendered another distinguished service in making available this series of articles.

Dr Morton S Biskind of the headquarters staff of the Council outlined the general series and assisted in editing the articles toward uniform expression and avoidance of excessive duplication

CLINICAL MANIFESTATIONS OF DYSFUNCTION OF THE ANTERIOR PITUITARY

HERBERT McLEAN EVANS, MD
BERKELEY, CALIF

Correct conceptions in almost every phase of the whole field of medicine rest on advances in experimental physiology. Belief in this view has been so well justified by the achievements of the last century that one may well claim the actual inauguration of modern medicine by the life work of such an investigator as Claude Bernard.

Endocrinology, a more or less well recognized clinical specialty, already possesses in some portions of its realm sufficiently precise and quantitative procedures for diagnosis and therapy, but in its other territories such tools are frequently so woefully lacking as to have led to a widespread feeling of insecurity in the field as a whole. Not only has a clinic of endocrine diseases been born in the last few decades, but a host of skilfully contrived and fruitful laboratory studies has been given to the world, the present moment is an appropriate one for inquiry as to the aid given clinical endocrinology by the results of modern experimental biology. The series of articles in *THE JOURNAL* of which this is the first is devoted to this end.

The experimental biology of the last decade, which has been directed toward securing both overfunction and underfunction of the pituitary gland, has now finally given adequate grounds for belief in the existence of at least five separate internal secretions or hormones of the anterior pituitary—the somatotropic,¹ the gonadotropic,² the thyrotropic,³ the mammatropic,⁴ and the interrenotropic⁵ hormones. It is felt that the relation of these achievements to clinical medicine will be disclosed most successfully by the discussion of pituitary and related diseases with reference to the existence of proved deficiency or excess of these five known substances, for the recognition of which there are now specific tests.

I GROWTH HORMONE

Underproduction—Dwarfism. The first solidly won achievement of experimental research in the pituitary field may be described as the production of dwarfism and sexual infantilism following hypophysectomy in young animals, especially puppies. Mammals are unable to continue to increase in skeletal dimensions after hypophysectomy. The surprising stasis in the growth of the long bones can be confirmed in a few weeks by roentgenograms. They are similarly unable to increase their body substance strikingly, as determined by post operative weighings.⁶

From the Institute of Experimental Biology, University of California. For collaboration in this work the author is indebted to his associates Drs Miriam E Simpson, W R Lyons and E H Rynearson.

1 Somatotropic hormone—the growth hormone, phyone, antuitrin G, somatotropin.

2 Gonadotropic hormone—gonad stimulating hormone, glandular heb, sex hormone of the anterior lobe, gonadotropin.

3 Thyrotropic hormone—thyreotropic or thyroid stimulating hormone, thyrotropin.

4 Mammatropic hormone—lactogenic hormone, mammary-stimulating hormone, galactin or prolactin, mammatropin.

5 Interrenotropic hormone—adrenotropic, adrenolatropic or adrenocorticotrophic hormone, interrenotropin.

6 In cases in which the hypophysectomy has injured the contiguous hypothalamus adiposity may result (Camus and Roussy Smith) and it is to be borne in mind that weight increases after a complete hypophysectomy may be thus explained. Selye states that a slight and temporary capacity for growth is present if the hypophysectomy has been done on very young animals.

Cases of human dwarfism due to defective function of the anterior lobe have been designated by Erdheim as *nanosomia pituitaria*. It is not improbable that any and all forms of dwarfism are directly caused by inadequate pituitary function, regardless of the ulterior cause. Cretinic dwarfs are apparently the result of the depression of pituitary function due to thyroid subnormality, and restoration of their growth can be effected either by the administration of thyroid (which can be understood to stimulate the hypophysis) or by direct treatment with pituitary extracts.

The growth of hypophysectomized rats or puppies can be readily produced by the use of anterior lobe extracts, these may now be freed sufficiently from contaminating hormones as to produce normal growth while the thyroids, sex glands and adrenal cortex remain atrophic.

The classification of human dwarfism is not completely satisfactory at the present time. Part of the difficulty is due to the fact that the defective growth may or may not be associated with sexual infantilism. Diminutive individuals with adult proportions exist, more often the childhood proportions are retained, the upper length of the body exceeding the lower. The latter cases are usually sexually delayed or infantile. In some of them a peculiar, unexplained, senile appearance manifests itself (progeria).

Human dwarfism has been treated with pituitary extracts by several careful workers⁸ who have reported that children who had ceased growth, or were growing at a subnormal rate, resumed normal growth or even exceeded the growth rate normal for the age at treatment.

Deficiency of Growth Hormone in Adult Life It has thus far been impossible for the experimentalist to eliminate the growth hormone only, either in infantile or in adult life, nor are there adequate grounds for believing that in human hypopituitary states only the growth hormone has been eliminated. In 1914 the Hamburg pathologist E. A. Simmonds reported a cachectic and rapidly wasting state associated with the finding at necropsy of complete destruction or sclerosis of the pituitary. Animals deprived of the pituitary frequently develop a similar cachectic state. Our reason for believing that the growth hormone is not concerned here rests on the fact that although such animals can be forced to grow with growth hormone extracts, the cachexia continues. The cachexia is relieved by crude anterior lobe extracts but not by adrenal cortical extracts, so that it has no affinities with Addison's disease.

The role of the growth hormone in adult life is thoroughly obscure. The return of hair over shaved areas is speedier in its presence than in its absence. Brugsch (1927) has described a disease, *akromikrie*, which he considers the converse of acromegaly. It is characterized by thinning of acral parts, subnormal growth, falling hair, thirst, amenorrhea and acrocyanosis.

The growth hormone is not more abundant in the anterior lobes of young calves than in those of adult cattle, and it is certain that the hormone is employed in the physiologic mechanism of the body throughout life.

Overproduction—Gigantism and Acromegaly Clinicians felt secure in the interpretation that general symmetrical overgrowth (gigantism) and also an asymmetrical disfiguring overgrowth in adult life (acromegaly) were both due to overactivity of the anterior hypophysis. The pituitary was found to be hypertrophied in both conditions, in acromegaly the gland is enlarged, essentially owing to increase of the eosinophilic cells.⁹ Any insecurity in this interpretation may be said to have ended with the experimental production of gigantic rats and of acromegalic dogs.

No source for growth hormone preparations other than anterior lobe tissue itself has yet been discovered. The hormone has not been recognized as yet in the blood or urine in acromegaly, nor has the claim of its presence in the urine of pregnancy been substantiated.

II GONAD-STIMULATING HORMONES

In 1926 Zondek and Aschheim and, independently, P. E. Smith discovered that anterior pituitary tissue implanted under the skin or intramuscularly in immature rats or mice brought about a development of the ovaries and other signs of precocious sexuality within four days. The ovarian picture was complex. Along with typical follicular growth, ovulation and the formation of corpora lutea there occurred a premature lutein transformation of the walls of many ovum-containing follicles. The growth of the ovarian follicles is now referred to a specific one of the two gonadotropic hormones which it is thought are secreted by the pituitary gland. It has been called "the follicle-stimulating hormone". The development of lutein tissue is regarded as an effect of another gonadotropic substance—the luteinizing hormone.¹⁰ Zondek and Aschheim quickly extended their discovery to the domain of clinical medicine by detecting gonadotropic hormone in the urine of pregnancy, later they found gonadotropic substance in body fluids and tissues in other conditions. These authors early showed that predominantly follicle-stimulating effects were produced by the principle found in menopause urine¹¹ but that these were combined with luteinizing effects when pregnancy urine¹² was given. The Berlin investigators unfortunately spoke of both urinary substances as anterior lobe substances, and much confusion in the literature has been created thereby. The gonad-stimulating substance present in pregnancy urine does not exactly resemble any chemical fraction that has been hitherto secured from anterior lobe substance, a long series of studies, beginning with that of Evans and Simpson in 1929, has shown it to be less efficacious than pituitary implants.

9 This was first recognized by Benda (1900) and securely established by the studies of Fischer (Die Beziehungen des Hypophysentumors zu Akromegalie und Fettsucht, Wiesbaden, Bergmann, 1920) and of Bailey and Cushing. The histophysiology and histopathology of the anterior hypophysis is in a thoroughly unsatisfactory state. Such previously well established concepts as pregnancy and castration cells are either now denied validity or described as differing in different animal forms.

10 The ovarian effects of gonadotropic substances from various sources and from various treatments of anterior lobe tissue are not yet completely understood. The terms follicle stimulating and "luteinizing" may turn out to be somewhat inappropriate when more is learned of their mechanism of action.

11 Menopause urine, prolactin A, follicle stimulating urine, castration prolactin, castration urine.

12 Pregnancy urine, prolactin, chorionic prolactin, pregnancy prolactin, urinary human antuitrin S, follicle.

7 P. E. Smith (Increased Skeletal Effects in A. P. Growth Hormone Injections by Administration of Thyroid in Hypophysectomized Thyroparathyroidectomized Rats, *Proc. Soc. Exper. Biol. & Med.* 30:1252 [June] 1933) has shown that an enhanced growth of such animals can be obtained by simultaneous administration of thyroid extracts with such preparations.

8 Shelton, E. K., Cavanaugh, L. A. and Evans, H. M. Hypophyseal Infantilism: Treatment with Anterior Hypophyseal Extract. Preliminary Study. *Am. J. Dis. Child.* 47:719 (April) 1934. Engelbach, W., Schaefer, R. I. and Brossus, W. L. Endocrine Growth Deficiencies: Diagnosis and Treatment. *Endocrinology* 1:250 (May-June) 1933.

or extracts of whole anterior lobe substance. Some of these differences are that

1 It cannot stimulate the growth of follicles and corpora in the ovaries of hypophysectomized animals¹³

2 It does not affect the development of the immature avian testis. This is readily produced by anterior lobe substance¹⁴

3 It has only slight effects on the monkey ovary—effects that do not lead to reddening of the sexual skin. This is produced by anterior lobe substance¹⁵

4 When administered to normal immature rats, no matter how frequently or in what doses, it rarely produces ovarian weights in excess of from 40 to 70 mg in ninety-six hours, whereas with anterior lobe substance increased effects are secured with increasing dosage the ovaries attaining from two to three times the weight stimulated by pregnancy urine¹⁶

Struck by the ineffectiveness of the gonadotropic substance in pregnancy urine in hypophysectomized animals and its partial effectiveness in normal immature ones, Evans, Simpson and Austin extracted anterior lobes in various ways in order to discover the substance needed to make the factor in pregnancy urine maximally effective. They designated this hypophyseal substance the "synergist." When combined with the gonad-stimulating principle of pregnancy urine normal gonadotropic effects were secured even in hypophysectomized animals¹⁷. It is highly interesting that Leonard and Smith,¹⁸ by the simple addition of the principle in menopause urine to that in pregnancy urine, have secured similar results. A chemical separation of anterior lobe extracts into follicle-stimulating and luteinizing components was at least partially made and announced as early as 1930 by Fevold, Hisaw and Leonard. Wallen-Lawrence¹⁹ has also successfully fractionated anterior lobe substance into extracts with similar effects. Fevold and Hisaw²⁰ have recently suggested that their follicle-stimulating hormone is identical with the synergist shown to be essential for completing the action of the gonadotropic factor of pregnancy urine.

It would appear therefore, that in the menopause and in pregnancy the body fluids contain types of gonadotropic hormone that are similar to, if not identical with, types that can be secured by chemical treatment of the pituitary gland. Combinations of either urinary component with the complementary gland component behave synergically. More than this cannot be said at the present time, nor will it be well to hazard a guess as to the identity of substances still incompletely known both biologically and chemically.

There are reasons for believing that the gonadotropic factor of the urine of pregnancy arises through the function of chorionic tissue and is not a product of the anterior hypophysis. These are that

1 The chorionic tissue of the placenta has large amounts of gonadotropic substance in it, as demonstrated by implantation or injection of extracts, whereas the anterior lobe of women dying in pregnancy has little or no gonadotropic hormone in it (Philipp)

2 The same hormone is present in high amounts in all types of chorionic tissue growth, especially hydatidiform mole and chorionepithelioma, whether in women or in men.

3 A rare case of hydatidiform mole has been described in which the body fluids were singularly lacking in this substance. Study of the uterine wall showed that the mole had been delimited from the maternal circulatory system by a massive fibrin boundary zone, conceivably preventing leakage of the hormone shown to be actually abundant in the mole tissue.²¹

4 The hormone content is high in the chorionic villi of extremely young ova as well as in the body fluids before the hypophysis shows histologic pregnancy changes.

For all these reasons it would seem best to designate this substance as chorionic gonadotropic hormone.²² Admittedly the proof of its production by the chorion, without contribution by the pituitary, could be secured only by quantitative studies of its secretion in a pregnant hypophysectomized monkey. It is almost certain that the placenta likewise manufactures the massive quantities of estrogenic substance produced in pregnancy.²³

The substance found in the blood stream and urine in underfunction of the ovary, in the menopause and following castration is certainly a product of the anterior pituitary. It would now appear certain that even the particular cells of the anterior lobe forming and storing this hormone are known—the basophils. The chain of evidence here is as follows:

1 The anterior lobe of castrated rats contains as a new feature the peculiar, enlarged signet-ring basophils or castration cells.

2 Such pituitaries contain an increased content of gonadotropic hormone.

3 The parabiotic union of a hypophysectomized female with a castrated male leads to the development of constant estrus and the presence exclusively of large follicles in the ovary of the female parabiont.²⁴

Follicle-stimulating urine and the hypophyseal synergist have both been administered to hypophysectomized male rats, and it is highly interesting that in both cases there occurred marked stimulation of the germinal tissue (the seminiferous tubules) without stimulation of the interstitial tissue or accessory sexual apparatus. In the male, these particular gonadotropic substances are hence quite purely gametogenic in their effects and without influence on the secretion of the testis hormone by the Leydig cells, whereas other anterior lobe extracts or chorionic gonadotropic hormone affect the testicular interstitial tissue and accessory organs predominantly.

Inadequacy of gonadotropic hormones—Hypophysectomy in young animals invariably leaves them sexually infantile, in fact, regression occurs from the stage of development of the genital system encountered

at the time of operation. Human infantilism is doubtless also in a large majority of cases referable to hypopituitarism. A satisfactory beginning has already been made in its treatment with gonadotropic hormones,²⁴ especially in delayed sexual development and cryptorchidism²⁵ in boys.

The relations between the pituitary and gonads are such that, while proper functioning of the latter may be prevented by inadequate secretion of the pituitary gonadotropic hormones, these hormones in other cases may be produced in normal amounts, but the gonads fail to respond. One can thus justifiably speak of primary and secondary hypogonadism. In the former case the gonad itself is at fault, as shown by abundant pituitary gonadotropic secretion in the blood stream, in the latter the pituitary gonadotropic function is at fault. The diagnosis is facilitated in women by the fortunate circumstance that both ovarian (estrogenic) and pituitary (gonadotropic) hormones are normally present in low amounts in the blood and urine after puberty.²⁶ Primary and secondary amenorrheas can therefore often be clearly segregated. Mazer and Goldstein ascribe some 80 per cent of cases of amenorrhea to hypophyseal insufficiency.

Gonadotropic therapy in amenorrhea, which will be more fully dealt with in a special article in this series, has on the whole been disappointing. As had been mentioned in the treatment of hypogonadism in the male, this has been largely due to the almost exclusive employment of the hormone found in the urine of pregnant women.

Underfunction of the hypophysis is not always expressed in the female as amenorrhea. It would appear from the successful results of therapy with the gonad-stimulating factor of pregnancy urine that Schroeder's disease (characterized by hypertrophic endometrium and excessive bleeding) may be the result of deficiency of gonadotropic hormone. The situation is further explained by the view that only one of the two hypophyseal gonadotropic hormones normally secreted is deficient, namely, the luteinizing hormone. The excessive amount of estrogenic substance produced by the cystic follicles undoubtedly causes endometrial proliferation, and an interruption of its production leads to the profuse uterine bleeding that

characterizes these cases. The improvement resulting from the administration of gonadotropic substance is apparently due to its luteinizing power. At any rate, the cysts or large follicles characterizing the ovaries of these women are luteinized by the treatment and the condition in the uterus, and consequent excessive bleeding is corrected. Long continued amenorrhea may be present in such cases if there is no intermission in the outpouring of estrogenic substance from the cystic follicles present. Such an amenorrhea has been described recently by Zondek, exactly the same conditions were found in the ovary and the uterus as in metropathia hemorrhagica.

Overabundance of gonadotropic hormone—*Pregnancy*. It is now well known that an outstanding characteristic of human pregnancy is the abundance in the blood and urine of estrogenic substance and of a gonadotropic hormone probably derived from the chorion. The increased quantity of estrogenic principle in these fluids appears somewhat later than does the rise in amount of gonadotropic hormone, though the estrus-inducing hormone lasts until birth, at which time it very abruptly diminishes. The gonadotropic hormone, on the other hand, is already abundant in the urine by the first missed period, constituting the well known Aschheim-Zondek test for pregnancy, a practically infallible means of recognizing gestation. The hormone reaches its maximum in the urine around the fourth or fifth month of pregnancy (from 5,000 to 20,000 mouse units per liter). The Aschheim-Zondek test has yielded outstanding service in the recognition of extra-uterine pregnancy. In the toxemias of pregnancy, extremely high amounts have been encountered in the last third of gestation.²⁷

Parturition. At birth, gonadotropic hormone disappears promptly from the maternal urine, even though this may not take place with such spectacular suddenness as the withdrawal of estrogenic substance. One thousand mouse units per liter of gonad-stimulating hormone has been found in the first day or two of the puerperium, though it is reported absent by the tenth to the fourteenth day. A continuing high titer in the puerperium is always associated with retained membranes. The same phenomenon is seen with death of the fetus, but failure to expel it, in earlier stages of pregnancy.

Hydatidiform Mole and Chorionepithelioma. Very extraordinary titers are given with the hydatidiform transformation of the chorion, and in chorionepithelioma amounts of from 100,000 to 520,000 mouse units per liter have been reported. The complete removal of the mole or malignant tissue usually leads to rapid disappearance of the hormone, but a few cases have been reported in which the hormone lingered unduly. These cases have been used to support the hypothesis of the formation of the hormone by the pituitary itself. The argument is unconvincing. Besides reservoirs for the very temporary storage of gonadotropic substance, the possibility of metastases which later regress must be considered. Should the test remain positive after a mole has been passed or removed, it must be repeated every fortnight until negative, and thence once a month for, say, three times, for malignant transformation may come late. If the test should continue to be positive a

24 But it is unfortunate that the majority of the reported cases concern only the employment of the principle in pregnancy urine. This substance as disclosed further in the present paper is markedly limited in its gonadotropic effects in all animals and especially in primates.

Treatment of Pituitary Infantilism with Antuitrin. *ibid.* 18: 233 (March April) 1934.

26 P. Wirz (H. V. H. and Amennorrhoe Ztschr. f. Geburtsh. u. Gynak. 104: 293 1933) finds only follicle stimulating hormone in the urine of small children the luteinizing factor appearing first at puberty to its appearance he attributes the onset of the cycle. In men the quantity is extremely small (Evans H. M. Simpson Miriam E. and Austin P. R. The Recognition and Comparison of Prolan and Prolan like Substances. *J. Exper. Med.* 58: 561 [Nov.] 1933. Katzman P. A. and Doisy E. A. The Quantitative Determination of Small Amounts of Gonadotropic Material. *J. Biol. Chem.* 106: 125 [Aug.] 1934) but in women the quantity is large enough to be demonstrable at moderate dosage of the alcohol precipitate out of urine. Zondek says that on the average 5 mouse units per liter is present. Frank and his co-workers (Frank R. T. Goldberger M. A. and Spielman Frank. Present Endocrine Diagnosis and Therapy. *J. A. M. A.* 103: 393 [Aug. 11] 1934) find a definite variation with the cycle, a full mouse unit not being present in 40 cc. of blood until seven days before onset of the menses (Estrogenic substance is found by them also to vary increased excretion occurring about the tenth day and again about three days before onset of the next menstrual flow about 1,200 to 1,500 mouse units being excreted per month.) Kurzrok and his associates (Kurzrok, R. Kurzman I. J. and Creelman M. Studies Relating to the Time of Human Ovulation. *Am. J. Obst. & Gynec.* 28: 319 [Sept.] 1934) describe a definite rise in gonad-stimulating hormone in blood just preceding or at the time of ovulation on days 10 to 13 of the cycle.

27 Heim K. Ergebnisse quantitativer Hormonanaysen bei Schwangerschaftstoxikosen. *Klin. Wchnschr.* 13: 1614 (Nov. 10) 1934.

month after removal of the uterus for definite chorion-epithelioma, one may be sure of the growth of metastases

It is in cases of mole and chorionepithelioma that the hormone is found in the cerebrospinal fluid, it is not detectable in the liquor in normal pregnancy

Testicular Tumors Testicular tumors of particular types (the classic work is Chevassu's), which are now recognized as teratoid though they possess undifferentiated or embryonal cells (embryonal carcinoma and sometimes true chorionepithelioma), also give astonishingly high amounts in the urine. We have ourselves seen a case in conjunction with Hinman and Powell in which the urine shortly before death contained one million rat units per liter. Several cases of retroperitoneal and mediastinal locus of these tumors with complete freedom of both testes have now been reported. As in malignant transformation of the chorion in the female, the following of the titer in the urine is important as indicating local or metastatic recurrence.

Castration Hypogonadism and the Menopause It has been found that women who for any reason have partial or complete loss of ovarian function often²⁸ excrete considerable amounts of castration gonadotropic hormone, e. g., after the menopause after operative removal of the gonads, after roentgen castration or after hypogonadism resulting from pathologic processes in the gonads. Other amenorrheas due to unexplained ovarian insufficiency and the amenorrhea of lactation belong here. Zondek, Wirz and others agree that urinary titers of more than 100 mouse units per liter indicate absence of function of the ovary. Osterreicher²⁹ finds from 80 to 300 mouse units per liter in the urine in both castration and the menopause. The hormone is also found in the urine of castrated men.

Genital Cancer Zondek's early studies convinced him that malignant tumors of the genital tract were three or four times as prone to be associated with the presence of urinary gonadotropic hormone as were benign growths. In fact he felt that some indication of the malignancy of a genital neoplasm could be secured by implanting fragments of the tumor tissue into immature rodents, if strongly positive malignancy was indicated. But neither this procedure nor the titration of urines for gonadotropic hormone has yielded the same spectacular service in genital cancer afforded by similar tests of the body fluids in mole and chorionepithelioma.

Miscellaneous Conditions with Increased Hormone Riley and his associates³⁰ have shown the presence of the menopause hormone in the urine in migraine, its appearance being correlated with the seizures. Kraus³¹ has shown the hormone in cases of brain tumor and in 60 per cent of women with increased intracranial pressure. In skin diseases, e. g., pruritus vulvae and acne rosacea, the urinary hormone has also been reported.

III LACTOGENIC HORMONE

The invariable association of milk secretion with reproduction in the female was itself an a priori reason for supposing that the hormone characteristic of preg-

nancy, that of the corpus luteum (progesterone), was responsible for the mammary changes. Yet it would appear that nothing is better established than the non-concern of luteal function with mammary activity. The latter is now known to be due primarily to the secretion of another special hormone (prolactin, or the lactogenic hormone) by the anterior lobe. Experimental biology may be said to have demonstrated

1 The necessity of estrogenic substance³² to provide the growth stimulus to the mammary gland

2 The fact that the estrogenic factor is limited in its effects—it causes an unfolding of the duct system but not development of secretory alveoli

3 The non-necessity of progesterone³³ in mammary physiology

4 The invariable dependence of the mammary gland for functional development on prolactin

5 The inhibition of prolactin secretion by estrogenic substance

It is probably safe to say that all mammary glands have been exposed to estrogenic hormone, even if only temporarily, during fetal life and immediately post partum. The majority of new-born infants show a mammary growth spurt, and often secretion, following the elimination of estrogenic substance from the system in the first week of life. The preliminary action of estrogenic hormone, its withdrawal or diminution, followed by a temporary prolactin secretion, would seem to explain the long debated phenomenon of witch's milk.

The cyclic changes in the breast showing maximum development, and often secretion, at the time of menstruation have as their best explanation a cyclic secretion of prolactin. Cases have been described wherein milk is secreted regularly during menstruation or in place of menstruation, at the usual intervals.³⁴ The fact that breast growth and lactation may follow ovariectomy or the menopause forces one to the conclusion that continued stimulation by estrogenic substance is not necessary to the breast and that prolactin may continue to be effectively secreted long after the influence of the estrogenic factor has disappeared. Cows lactate for two years following ovariectomy, and women have been known to do so for several months. The stripping of these spontaneously lactating glands would probably prolong lactation by virtue of a reflex prolactin secretion³⁵ as well as by preventing regression due to alveolar stagnation. The fact that one fourth of all women show parenchymal breast hypertrophy following the menopause, instances of senile lactation, cases of prolonged lactation (especially those associated with amenorrhea, uterine regression or fibroid) point to hypersecretion of prolactin or at any rate to a prolactin effect, which to some extent may be due to the removal of the inhibition exercised by estrogenic substance.

In pregnancy or pseudopregnancy, a gradual continuous growth of the breasts is substituted for the cyclic changes. The fetus plays no important role, if

32 A generic term used throughout this series to avoid the confusion entailed by the current employment of its many alleged synonyms. The reader is referred to an editorial, *The Nomenclature of Glandular Products* (THE JOURNAL Oct. 13, 1934, p. 1152) in which this subject is discussed.

33 Progesterone corporin hormone of the corpus luteum

any, in mammary physiology and the chorion probably need only be considered because of its contents of estrogenic and gonadotropic hormones. Guinea-pigs and women may continue pregnancy and deliver and suckle their young following ovariectomy,³⁶ but if an animal is hypophysectomized during pregnancy the mammary growth is inhibited and even though a small amount of milk may be present after parturition the breasts quickly atrophy.³⁷ It is not unlikely that prolactin is alone responsible for the growth of the breast in pregnancy and in the puerperium, since with prolactin one may obtain full development and lactation in animals ovariectomized after reaching sexual maturity.³⁸ Estrogenic substance depresses prolactin secretion during pregnancy, the expulsion of the placenta, whether at term or prematurely, releases that inhibition, and full growth of the breasts and lactation follow.³⁹ Failure to lactate following parturition may in some instances be explained by an excess of estrogenic substance in the system or simply by insufficient prolactin. The continuance of secretion of estrogenic hormone in cases of retained membranes amply explains the impairment of mammary function observed in this condition.

The clinical and postmortem observations in gynecomastia are variable and confusing. Aside from being found in true gynandromorphism, where it might be expected, it is also associated with tumors of the testis known to contain estrogenic substance, and with pituitary, adrenal and pineal tumors. It is very difficult as yet to evaluate degrees of gynecomastia in terms of estrogenic substance and prolactin, respectively. However, if the organism were saturated with estrogenic hormone and the anterior lobe did not secrete prolactin no parenchymal growth over and above nipple and duct hypertrophy would occur. It is not unlikely that the presence of chorionepitheliomas with their high contents of estrogenic and gonadotropic hormones is inhibitory toward the prolactin secreting cells since only about 6 per cent of these cases show gynecomastia.⁴⁰

Since pituitary dysfunction rarely manifests itself with respect to a single hormone, it is not surprising that abnormal mammary hyperplasia with or without lactation has been found associated with gigantism or acromegaly in both sexes indicating that at least two of the established anterior lobe hormones are in excess. Male impotence as well as amenorrhea, accompanied by abnormal breast development and lactation, may in some instances be due to hypogonadotropic hormone secretion coupled with oversecretion of prolactin, while lactation in sexually normal males with pituitary tumors implies hyperactivity of the prolactin secreting cells without impairment of the gonadotropic hormone secretion.

Until the physiopathologist duplicates the various abnormal breast hyperplasias with hormones in such a form as the hypophysectomized monkey, it would be better to abstain from too much conjecture regarding hormonal etiology. Animal experiments suggest how-

ever, that abnormal nipple or duct growth may be accomplished by excess of estrogenic hormone alone, whereas abnormal alveolar hyperplasia may require preliminary stimulation by estrogenic substance followed by prolactin. By injecting estrogenic substance to inhibit prolactin secretion, Mazer⁴¹ obtained some measure of regression in cases diagnosed by the effect of treatment as lobular hyperplasias. Geschickter and his colleagues⁴² have partly reproduced the picture of fibro-adenoma in the male monkey by injections of estrogenic substance and prolactin.

One is tempted to search for hormonal explanations of the well known fact that the great bulk of benign mammary tumors occur before, while most malignant growths occur after, the menopause. Transplantable or spontaneous mammary tumors are partly inhibited in their growth by hypophysectomy and are accelerated by pituitary injections.⁴³ The slightest indication of a relationship between prolactin and the incidence or proliferation of malignant conditions will undoubtedly restrain the zeal of those clinicians anxious to improve breast function.

For a better understanding of abnormal breast conditions, a suitable test for prolactin in the body fluids is needed. With simultaneous assays of estrogenic and gonadotropic hormones and prolactin in bloods and urines, the gynecologist should be able more accurately to decide on the hormonal relationships in any given mammary condition, and the actual need of nursing mothers for prolactin therapy.⁴⁴

IV THYROTROPIC HORMONE

The discovery of thyroid-stimulating effects from anterior pituitary substance was made simultaneously and independently by Loeb and by Aron in 1929. It is now known that these thyreotropic⁴⁵ or thyrotropic effects are due to a specific hormone of the anterior lobe, i.e., to a substance which, although not yet finally purified, does not give the other effects of anterior lobe implants or extracts (somatotrophic, gonadotropic and the like). As will be disclosed in a special paper of this series, its first approximate purification was achieved independently by Junckmann and Schoeller and by Loeser in 1932. The researches of the Aron group at Strasbourg, of Jansen and Loeser and their co-workers at Freiburg, and of Collip, Anderson and their associates at Montreal have done much to elucidate the biologic effects of this substance. The thyrotropic hormone exerts its action only in the presence of the thyroid gland, a complete thyroidectomy obliterating any and all of its specific effects.

Underproduction of Thyrotropic Hormone—Pituitary ablation is invariably followed by hypothyroidism, conditions of underfunction of the pituitary could therefore be followed by hypothyroid states. One may therefore justifiably ask to what extent cretinism or myxedema may be regarded as being primarily pituitary and only secondarily thyroid disorders, i.e., due to inadequate amounts of thyrotropic hormone. Unfortunately the titration of the body fluids for thyrotropic

45 The term was first suggested by Wiesner and Crew.

hormone is not in as satisfactory a state as that concerning the gonadotropic hormones. It must be confessed that although Aron⁴⁶ and his associates feel that this titration can be effected and that the body fluids are indeed enormously high in thyrotropic hormone in myxedema,⁴⁷ his results are under dispute, Marie Krogh⁴⁸ denies their validity entirely. Paal⁴⁹ and Nielsen⁵⁰ both report the hormone in the urine. Giedosz,⁵¹ while finding it in the urine, finds it in a motley array of disorders not specifically related to thyroid or pituitary disorders.

Overproduction of the Thyrotropic Hormone—It has already been noted that Aron feels that one can recognize very high titers of this substance in many cases of myxedema, and it is interesting that the same observer reports his lowest recorded titers (subnormal amounts) in cases of exophthalmic goiter, which he is hence inclined to classify as primary thyroid overactivity not induced by overabundant thyrotropic substance.⁵²

The discovery of an antithyrotropic hormone by Anderson and Collip, and the extension of this discovery to the detection of other anterior pituitary anti-hormones (antigrowth, antigonadotropic, antiketogenic) has introduced a new epoch of theoretical as well as clinical research. The amelioration of exophthalmic goiter by antithyrotropic hormone has already been reported, it being fortunate that the thyroid secretion does not oppose or modify the effects of antithyrotropic hormone. Collip's⁵³ conception that all hormones are accompanied by and "buffered" by a normal blood content of antihormone, and his statements that the antihormones do not arise concurrently with other known antibodies, all indicate that the phenomena are distinct from those hitherto studied in the field of immunity.

V INTERRENOTROPIC HORMONE

There is both experimental and clinical evidence to support the concept of an interrelationship between the anterior pituitary and the cortical tissue of the adrenal gland. Houssay⁵⁴ and Shumacker and Firor⁵⁵ have both recently and rather comprehensively reviewed this subject.

46 Aron M. Le titrage des hormones prehypophysaire dans l'urine humaine son interet dans l'exploration fonctionnelle des diverses glandes endocrines. *Bull Acad de med Paris* 111: 273 (Feb 20) 1934.

47 Aron's observations if substantiated will prove that many if not most cretinic and myxedematous conditions are primary thyroid disorders just as the overabundance of gonadotropic hormone in the menopause and the primary amenorrheas indicate primary inability of the ovary to respond to gonadotropic hormones that are normally or even excessively present. Aron's results also explain the unfavorable results in the few cases in which thyrotropic therapy has been tried in myxedema. Schittenhelm and Eisler have for instance injected from 600 to 1 000 guinea pig units daily of the thyrotropic hormone without significant improvement.

48 Krogh Marie and Okkels H. L'hormone thyreo-stimulante de la prehypophyse. *Compt rend Soc de biol* 116 255 (April 12) 1934.

49 Paal H. Ueber Hormothyrin das Schilddrusenanregende Hormon des Hypophysenvorderlappens. *Klin Wchnschr* 10: 2172 (Nov 21) 1931.

50 Nielsen, Herman. Ein Thyreostet durch Harninjektion in Kaninchen. *Klin Wchnschr* 12 508 (April 1) 1933.

51 Giedosz B. Ueber thyreotrope Substanzen im menschlichen Harn. *Klin Wchnschr* 13 1507 (Oct 20) 1934.

52 It may be felt that such a deduction can hardly be allowed conclusive validity for it is conceivable that a hypertrophied thyroid could demand and utilize such large amounts of the thyrotropic hormone as to depress the normal titer in this substance. On the other hand Aron and others have shown that thyroxine renders thyrotropic hormone inefficient and thyroid overactivity might therefore automatically control itself in the normal mechanism quite apart from the thyrotropic antithyrotropic balance. The improvement in some cases of exophthalmic goiter following roentgen therapy of the pituitary reported by Merklin and Aron (1933) and by Peters (1934) lends inadequate support to the conception of pituitary exophthalmic goiter.

55 Shumacker H B and Firor W M. The Interrelationship of the Adrenal Cortex and the Anterior Lobe of the Hypophysis. *Endocrinology* 18 676 (Nov Dec.) 1934.

Hypopituitary States—Following hypophysectomy there is a rapid and extensive atrophy of the adrenal cortex, which can be restored by the use of pituitary implants or injections of extracts but not by injecting cortical hormone. It seems certain that this repair is due to a special hormone of the anterior lobe, the adrenotropic or, better, adrenocorticotrophic or interrenotropic hormone.⁵⁶ Following unilateral adrenalectomy in normal animals there is a marked compensatory hypertrophy of the remaining adrenal, which does not take place in a hypophysectomized animal. In clinical conditions such as pituitary cachexia and dwarfism the adrenals have been reported as disproportionately small. In anencephaly the hypophysis is small or absent and it is interesting that there is also hypoplasia of the adrenal cortex.

Hypocortical States—Adrenalectomized rats can be made to grow by adequate treatment with cortical hormone, but this is not the case if the animal has been hypophysectomized. In Addison's disease histologic changes occur in the pituitary gland, chiefly a diminution in the number of basophils. Similar changes have been found in the pituitary of an adrenalectomized dog. The treatment of Addison's disease with pituitary extract has been reported by Wilder.⁵⁷

Hyperpituitary States—The implantation of anterior pituitary tissue or injection of pituitary extracts into normal animals brings about a marked hypertrophy of the adrenals. This is apparently due to the same hormone that repairs adrenal-cortical atrophy after hypophysectomy, and the preparation of the hormone in a rather pure state has been reported.⁵⁸ The thyroid is necessary in this pituitary production of adrenal hyperplasia, although the thyrotropic hormone does not seem to be the essential cause of it, for pituitary extracts devoid of thyrotropic effects are able to produce the adrenal enlargement, and the enlargement cannot be produced by administering the thyroid hormone.⁵⁹ In cases of acromegaly, adrenal hyperplasia and cortical adenomas are often present, and one case has been reported in which an acromegalic girl suddenly developed hirsutism, interpreted as an adrenal effect.

Hypercortical States—In addition to being essential for life, the adrenal cortex seems definitely related to the reproductive and integumentary system, as is well illustrated in a rather well defined group of changes produced by certain cortical tumors (interrenalism).⁶⁰ It remained for the acumen of Harvey Cushing to discover that a group of these cases is produced by basophilic adenoma of the pituitary (Cushing's disease).⁶¹ Similar pictures are given by arrhenoblastomas.

56 If the carbohydrate upset caused by the anterior lobe extracts should be established as an epinephrine diabetes (hyperepinephrism) thus produced by a pituitary hormone it may then be appropriate to speak of the latter as the adrenomedullotropic or chromaffinotropic hormone.

of the ovaries^{61a} The many symptoms common to these groups form strong substantiation for a special pituitary-adrenal-gonadal interrelationship The titration of the body fluids for the gonadal and gonadotropic hormones in these various conditions has not yet been adequately undertaken⁶² Pituitary transplants have been found to have an effect on the reproductive system of adrenalectomized animals, but cortical hormone did not affect hypophysectomized animals

VI METABOLIC HORMONES

In addition to the metabolic effects that have already been mentioned in the discussion of the thyrotropic and interrenotropic hormones, there have been studies made on some special relationships of the anterior hypophysis to metabolism These deal largely with the metabolism of carbohydrate and fat, and to a less extent of protein The interpretation of such studies is especially difficult because of the many species used the varying technics of operation, the many types of extracts injected, the different methods of chemical analysis, and the acknowledged interrelationship of many factors other than the pituitary gland involved in general metabolism

Until recently it seemed most likely that water metabolism was controlled solely by hypothalamic centers to which it was admitted the posterior lobe had a relation not wholly understood, the outstanding fact being the therapeutic control of diabetes insipidus with posterior lobe extracts Evidence of a relation of the anterior lobe to water metabolism has recently been furnished I shall not discuss this but concern myself with the more carefully investigated but perhaps equally obscure relation of the anterior lobe to carbohydrate, fat and protein metabolism

Carbohydrate Metabolism—This field may be considered as having been opened by the announcement of Houssay and Magenta in 1924 that hypophysectomized dogs have a markedly increased sensitiveness to insulin This has been confirmed abundantly, although it awaits thoroughgoing elucidation In 1930 Biasotti and Houssay extended to mammals an experience with toads to the effect that hypophysectomy lessens the severity of diabetes from pancreatectomy and that after such double operations an intensification of the diabetes ensues from anterior lobe but not from posterior lobe implants These announcements, sufficiently spectacular, suffered temporary neglect, but energetic refutation or confirmation and extension of the Houssay phenomena is now being undertaken In 1932 came the independent announcements by Evans and his co-workers and by Houssay of the production of hyperglycemia and glycosuria in normal animals by injection of anterior pituitary extracts

This, which is perhaps the most deeply interesting field of pituitary research, continues to remain in the least satisfactory state, and clinical applications are premature

The studies that have been made on hypophysectomized animals may be summarized thus

1 A temporary glycosuria occurs which, it is generally agreed, is secondary to cerebral trauma rather than to the absence of the gland

61a Meyer Robert The Pathology of Some Special Ovarian Tumors and Their Relation to Sex Characteristics *Am J Obst. & Gynec* 22: 607 (Nov.) 1931

62 Though in one instance a substance having the effects of the testis hormone was found in a woman's urine (Simpson S L Clinical and Pathological Aspects of the Adrenal Glands *Proc Roy Soc. Med.* 27: 383 1934)

2 Hypoglycemia develops sometimes to the point of convulsions and death

3 The animals are markedly more sensitive to small amounts of insulin

4 The intensity of the diabetes of pancreatectomized dogs is lessened⁶³

5 The glycogen reserves are usually reported as diminished, though some reports of their normality have been made

As regards normal animals injected with pituitary extracts, one may state that

1 Disturbed carbohydrate metabolism is manifest by glycosuria hyperglycemia and decreased (diabetic) sugar tolerance curve

2 Houssay reports that these effects can still be secured in the absence of various organs including the thyroids, adrenal medulla gonads and sympathetic nerves Lucke states that the adrenal is essential

3 Most of the effects of the extracts require chronic injections for several days Only Lucke reports effects within a few hours

4 With the disturbance in carbohydrate metabolism there are associated disturbances in fat metabolism

The new conception that diabetes may be due to an overacting hypophysis⁶⁴ and not solely to inadequate pancreatic insular function is engaging, but the only conclusion now warranted is that, while there is some substance in the anterior pituitary that affects carbohydrate metabolism, the isolation of a special "diabetogenic" or "contra-insular" hormone has not yet been effected

Fat Metabolism—Hoffman and Anselmino (1931) and Magstris (1932) have secured from the anterior pituitary of beeves a material causing increased acetoneuria and simultaneous diminution of the neutral fats of the blood Bevin and Ling (1933) found increased acetoneuria of rats on a butter diet when injected with alkaline extracts of bovine anterior pituitary Extracts containing the thyrotropic hormone had been reported to give some of these effects, so that it is important that Black, Collip and Thomson⁶⁵ have recently secured the increased acetoneuria in thyroidectomized rats The evidence adduced up to the present time makes it probable that the "ketogenic principle" is indeed a separate hormone, for, although it contaminates growth and thyrotropic fractions, it may be secured in growth fractions free of thyrotropic and in thyrotropic fractions free of growth hormone, and it is said to be absent from the best adrenotropic preparations

Protein Metabolism—O H Gaebler^{66a} and Lee and Schaffer⁶⁶ have demonstrated the retention of nitrogen provoked by the growth hormone Houssay and his associates report that in phlorhizinized, hypophysectomized dogs, sugar and nitrogen excretion is markedly less than in unoperated on or thyroidectomized animals

63 Unfortunately not all published reports contain detailed necropsies

64 Some special students of the subject state that no pathognomonic lesions of the islets have ever really been established in diabetes mellitus But the newer studies of E J Kraus Lahhé and Petresco Glenn and others on the microscopic pathologic changes of the pituitaries of patients dead from diabetes are not more satisfactory Barnes and his co-workers have sought to improve diabetes by injections of estrogenic substance which would depress pituitary function diabetic treatment by radiation of the pituitary has been attempted with inconclusive results Selle and his co-workers (Selle W A, Westra J J and Johnson J B Effect of Irradiation of the Hypophysis on Experimental Diabetes *Proc Soc. Exper Biol & Med.* 31: 949 [May] 1934) were unable to affect diabetes in dogs by roentgen therapy

65 Black P R Collip J B and Thomson D L The Effect of Anterior Pituitary Extracts on Acetone Body Excretion in the Rat *J Physiol* 82: 385 (Oct. 17) 1934

66a Gaebler O H Some Effects of Anterior Pituitary Extracts on Nitrogen Metabolism Water Balance and Energy Metabolism *J Exper Med.* 57: 349 (March) 1933

66 Lee M O and Schaffer N K Anterior Pituitary Growth Hormone and the Composition of Growth *J Nutrition* 7: 337 (March 10) 1934

given phlorhizin⁶⁷ The former die in hypoglycemic crises whereas the latter do not Death can be prevented by feeding meat or sugar but not by feeding fat These observations are interpreted to mean that in the absence of the hypophysis there is an interference with the conversion of protein to carbohydrate

Varying results have followed the studies of the specific dynamic action in hypophysectomized animals and in clinical cases of hypopituitary disease No conclusions can be drawn from the work at this time

Clinical studies are not yet able to yield critical information regarding the relationship of the pituitary to metabolism Perhaps the earliest noted and best established phenomenon is the occurrence of glycosuria in about 40 per cent of the cases of acromegaly

The possible role of the pituitary in spontaneous hypoglycemia has been raised by Josef Wilder, who reported two cases with roentgen evidence of enlargement of the sella Were a contra-insular hormone available, it would be interesting to see its effect in those particular cases of this unfortunate condition in which no island tumor of the pancreas is found

While there can be no doubt that the pituitary gland plays a role in the metabolism of carbohydrates, fats and probably proteins, its modus operandi will not be sufficiently clarified until the researches of the immediate future are accomplished Its role may be to furnish specific hormones that act in conjunction with or as antagonists to other hormones In many laboratories efforts are being made to obtain these substances in at least partially purified form, though none are yet available for clinical use

CONCLUSION

The reader must not carry away the impression that the foregoing discussion comprises all that is known of the relations of the anterior pituitary with other glands and tissues of the body Indications of a special relation with the parathyroid are beginning to appear, and a role in erythropoiesis has been claimed An insular-pancreatotropic and an adrenomedullotropic hormone have been foreshadowed

The study of the possible derangement of many physiologic mechanisms in hypophysectomized animals has hardly begun Finally, this review has neglected completely the relation of the pituitary with the hypothalamus Future discoveries may irrefutably establish humeroneral mechanisms concerning which almost nothing is now known

It is perhaps somewhat surprising that not one of the five established pituitary hormones is accurately known chemically The protein nature of these substances has undoubtedly played a chief role in their intractability Yet in all cases a wide going purification has been attained, the minimal effective daily dose for test animals in the case of all them being below a milligram of substance

The desirability of increasing our power to estimate these materials quantitatively in the blood stream or urine could hardly be overstressed, and in the case of each one of them one must covet for the internist of the future the satisfaction now possessed by the gynecologist in his ability to determine the titers of estrogenic and gonadotropic hormones in the body fluids

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr Bernard Fantus The views expressed by various members are incorporated in the final draft for publication The series of articles will be continued from time to time in these columns.—ED

THERAPY OF UNCINARIASIS

Uncinariasis should be thought of in any case of hypochromic anemia with eosinophilia, though the absence of eosinophilia does not eliminate uncinariasis, as in very severe cases the eosinophil count may fall to the normal average or even below it A stool examination is called for, especially if there is also a history of exposure in infested regions While the dried smear examination may show the eggs, it is best to stir up a grain of feces with about 20 cc of saturated solution of sodium chloride After about fifteen minutes, the eggs floating on the surface are transferred, possibly by means of the mouth of an inverted test tube, to the microscopic slide

PROPHYLAXIS

The prophylaxis depends on proper disposal of the feces of all infected persons (sanitary latrines), avoidance of walking barefoot and thorough treatment of all infested persons, which, if possible, would greatly hasten the eradication of the disease

TREATMENT

The treatment of uncinariasis is a story in two chapters the expulsion of the worms and the cure of the anemia

PRESCRIPTION 1—Tetra Chloro-Ethylene Capsules

R. Tetra-chloro-ethylene

3.00 cc

Divide into six capsules

Label Take in the morning on empty stomach

1 *Anthelmintic*—Tetra-chloro-ethylene is the preferred agent at present It requires no preliminary measures, excepting that the patient have no breakfast Instead of this meal the patient takes 3 cc of tetra chloro-ethylene, preferably in capsules (prescription 1), followed immediately by a dose of 30 Gm of magnesium sulphate dissolved in a glassful of water If the patient believes he cannot swallow capsules, the tetra-chloro-ethylene is poured on a little sugar and is thus taken readily Children are given 0.2 cc for each year of age and 2 Gm of magnesium sulphate for each 5 Kg of body weight The patient should rest until the purge has acted, if it does not act within a few hours, a second dose of purgative should be taken After the bowel evacuation, the patient may eat preferably cooked cereal It is probably well to avoid the use of fats or alcohol just before and after administration of the drug, as these favor its absorption Its chief untoward effect is the occasional production of a transient dizziness, sometimes nausea, vomiting, headache, abdominal pains and malaise The patient should be warned against their possible occurrence They usually do not require treatment

After two weeks a stool examination should be made, and if no ova are found in flotation preparations the worms may be considered eradicated. If they are found, the treatment should be repeated, possibly with a dose of 4 cc of tetra-chloro-ethylene.

PRESCRIPTION 2—Reduced Iron Capsules

R Reduced iron 30.00 Gm
Divide into thirty capsules
Label Take two capsules three times daily after meals

2 *Hematine*—While there is a tendency to blood regeneration after expulsion of the worms, iron decidedly hastens this recovery, if given in large doses (e g, as in prescription 2)

3 *General Regimen*—Usually the patient may be permitted to continue with his occupation. Bed treatment is required only in extreme cases, especially in those with edema. An abundance of nutritious food is required in addition to the iron to favor rebuilding of the much depleted blood, and, no doubt, fresh air and sunshine are also useful in this direction.

THERAPY OF TRICHINIASIS

DIAGNOSIS

Marked eosinophilia should always lead one to suspect the possibility of some form of helminthiasis, though it must be remembered that eosinophilia may be due to many other conditions and that it is especially common in children. Some of the manifestations of the classic syndrome muscle pain, edema and fever might then suggest trichiniasis, the presence of which is rendered probable by discovery of the cysts in the suspected pork, and proved by the finding of the worms in the feces (difficult), in muscle tissue (after surgical excision under local anesthesia of a piece of the biceps, deltoid or gastrocnemius), or in the spinal fluid (after centrifugation) in cases presenting meningeal symptoms. The presence or absence of the trichiniasis skin test¹ strengthens the evidence for or against this diagnosis.

PROPHYLAXIS

Unfortunately, the usual microscopic inspection of fresh pork and pork products is no adequate criterion of freedom of the pork from trichinae. As complete cooking of pork will absolutely prevent the disease, every one should be educated to the importance of eating only thoroughly cooked pork and pork products. "Cook pork well" is the slogan of prevention, and it must be remembered that an adequate degree of heat (137 F) is slow in reaching the center of a thick piece of meat. Refrigeration kills the encysted larvae, but it must be at 0 F for forty-eight hours.

TREATMENT

1 *Active Purgation*—Even in cases not seen until six weeks after infection, active purgation should not be neglected. Mild Mercurous Chloride, in doses of 0.2 Gm, followed in six or eight hours by Magnesium Sulphate (30 Gm) and this by a colon flushing several hours later, might be repeated for several days, in the hope of sweeping out some of the worms that have not yet invaded the submucosa.

2 *General Care*—In cases presenting fever, it is fever regimen (q v) followed during convalescence by a long period of rest and highly nutritive diet.

3 *Relief of Clinical Manifestations*—(a) *Myositis*. Muscular pain, when well localized, might be relieved by limitation of motion by means of adhesive plaster strapping, provided it is not applied tightly enough to aggravate the muscular soreness. Morphine might be required, if milder analgesics fail (cf Therapy of Pain). It has been suggested that treatment with Calcium, as in the accompanying prescription, and parathyroid extract (from 20 to 40 units every twelve hours for not more than ten days) might hasten calcification of the cysts and thus shorten the course of the trichinal "rheumatism".

Calcium Lactate

R Calcium lactate 20.00 Gm
Lactose 40.00 Gm
Dispense in a box
Label Heaping teaspoonful in water before meals and at bedtime

(b) *Allergic Symptoms*. Urticaria, pruritus and the late edema, appearing about three weeks after the ingestion of the parasites, might possibly be benefited by Solution of Epinephrine (from 0.5 to 1 cc) injected intramuscularly and repeated as often as the rather transient improvement might demand.

(c) *Meningismus*. This might be ameliorated by lumbar puncture.

(d) *Failure of Respirations*. The failure of respirations from muscular involvement might call for treatment in a respirator.

DISCUSSION OF PREVIOUSLY PUBLISHED ARTICLES

DISTURBANCES DUE TO HEAT

To the Editor—May I submit the following comment on the article on the therapy of disturbances due to heat (THE JOURNAL, September 29, p 990).

Recent experience has fairly demonstrated that heat exhaustion is essentially dehydration. The human body is dependent on the vaporization of water from its surface for the dissipation of excessive heat. Water passing from a liquid to a vapor requires heat. This it takes from the body, thereby cooling it. Hence the call for water and more water, perspiration and more perspiration, depletion of water, dehydration and shock. There is no injury to the machinery of the body. All it needs is volume of water, and salt to maintain the proper osmotic balance. This dehydration precedes by considerable time any damage from hyperpyrexia. To still advise bleeding for sunstroke seems a bit out of date. The unconsciousness is due to brain anemia, and the demand is for fluid to fill the blood vessels and thus restore the needed pressure in the brain.

It is realized by all that by perspiration 8 or 10 pounds up to 20 pounds can be lost in one day. Most football players lose 6 or 8 pounds for each game, and still the coaches insist that they must not drink during the game.

The experiences at Hoover Dam at the Los Angeles aqueduct and at numerous other places in California and elsewhere demonstrate this principle. At these points the prophylaxis is the same as that advised by Dr Fantus and he has covered it very well. If he had simply continued the same fundamental principle into his therapeutics he would save many lives and many days of illness because it has been repeatedly demonstrated that intravenous salt or dextrose solution will by filling the empty blood vessels almost immediately put patients on their feet.

Pathologists find the heart and major blood vessels empty at autopsy and the skin suffused with what little blood is left in the body. This dusky cyanotic picture has always suggested bleeding and this undoubtedly is the basis of the advice in this article to draw blood in the asphyxial form of heat exhaustion.

¹ McCoy, O R. Miller J J., Jr. and Friedlander R D. The Use of the Intradermal Test in the Diagnosis of Trichiniasis. J Immunol 24:1 (Jan) 1931.

However the mechanics of the condition indicates that instead of depletion there is a demand for fluid to fill the central blood vessels. The essential mechanics is that heat dilates capillaries and increases the permeability and keeps on dilating them and drawing blood from the heart and large blood vessels until cyanosis appears. The capillary permeability sometimes is so great that ecchymoses result.

The records at Hoover Dam are striking and are summarized as follows:

Summer of 1931 From 100 to 150 cases (no record), 17 deaths

Summer of 1932 Seven cases, no deaths (Prevention and treatment based on the dehydration principle were instituted in the spring of 1932)

Summer of 1933 Thirteen cases, no deaths

Summer of 1934 Very few cases, no record, no deaths

A record of these experiences is given by Dr R O Schofield, "Heat Prostration—Its Treatment at Boulder Dam," in *California and Western Medicine* 41 83 (Aug) 1934

CORNELIUS VAN ZWALENBURG, M D, Riverside, Calif

COMMENT — Unfortunately, the pathology of an established case of sunstroke is not simple dehydration, as is shown by the fact that mere rehydration is usually not sufficient for cure. Even though dehydration might have been the original factor, secondary changes are present in sunstroke, as is evidenced, for instance, by the postmortem changes, among which multiple hemorrhages are quite common. Bleeding, of course, is not advocated and should not be resorted to until after thorough and complete rehydration. It is only then, and especially if symptoms of increased intracranial tension or of pulmonary edema manifest themselves, that bleeding might be thought of.

THERAPY OF CARBUNCLE

Dr Sumner L Koch presents the following much simpler treatment for carbuncle than that described in *THE JOURNAL*, Oct 6, 1934, page 1066

It is my belief that carbuncles, particularly small carbuncles, should be treated in the early stages by the application of warm wet dressings. If spread of inflammation is not halted and drainage does not take place promptly, the infected area should be opened, but the operative treatment should be confined to incision, undercutting of the flaps and the insertion of soft drainage material, such as petrolatum gauze or rubber tissue, simply to keep the flaps from falling back in place and immediately becoming adherent again to the surface from which they had become separated. Surgical treatment should be followed by the continued application of warm wet dressings until the acute inflammation subsides. When the acute inflammatory process has subsided, the use of dressings saturated with surgical solution of chlorinated soda undoubtedly is helpful in dissolving the necrotic tissue and so taking away the most important part of the culture medium for the bacteria present.

Until we can impress our students with the fact that tissues, whether normal or infected, are delicate living structures that need to be handled with every possible care and protected from every possible insult and injury, we shall fail in our purpose. The sooner we can get rid of the old idea that phenol

iodoform gauze, pastes and salves are helpful in the treatment of an infectious process associated with sloughing and necrosis of tissue, the better off we shall be.

COMMENT—*Simplex est sigillum veri* (the simple is the sign of the truth) is probably correct in medicine as well as in philosophy

RINGWORM OF THE HAIRY PARTS

To the Editor —Referring to the article on the treatment of trichophytosis (The Therapy of the Cook County Hospital) appearing in *THE JOURNAL*, Sept 15, 1934, page 832, attention should be directed to the paragraph headed "Ringworm of the Hairy Parts." The treatment there recommended consists of temporary epilation by means of roentgen rays, thallium or manual extraction. Epilation therapy is requisite in only certain forms of trichophytosis capitis—chiefly that caused by *Microsporon Audouini*. In many cases of ringworm of the scalp, the causative fungus is an "animal-borne" fungus, producing inflammatory and kerion-like scalp lesions in children, these do not require depilation, as the large majority of them are readily curable by means of local antiseptic ointments.

Recently this fact was brought to the attention of readers of the Year Book of Dermatology and Syphilology (Year Book Publishers, Chicago) for 1933, page 267, by its editors, in a comment following an article on ringworm by R. L. Gilman. A more detailed discussion will be found in an article by George M Lewis Ringworm of the Scalp. A Report of Three Cases Due to the *Microsporon Lanosum* with a Tendency to Spontaneous Recovery, *Arch Dermat & Syph* 29 890 (June) 1934

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.  RAYMOND HERTWIG, Secretary

KELLOGG'S ALL-BRAN

FLAVORED WITH MALT, SUGAR AND SALT

Manufacturer—Kellogg Company, Inc., Battle Creek, Mich.

Description—Cooked wheat bran flavored with sucrose, malt extract and salt

Manufacture—Wheat bran is cooked under steam pressure with water, sucrose, malt syrup and sodium chloride. The mixture is partially dried, shredded, toasted, cooled and packed in wax paper lined cartons

Analysis (submitted by manufacturer) —

	per cent
Moisture	2.3
Ash	8.2
Sodium chloride	3.1
Fat (ether extraction method)	3.2

Calories—3.4 per gram 97 per ounce
Vitamins—One ounce furnishes 45 Sherman and Chase vitamin B units

Claims of Manufacturer—Bran fiber is more resistant to disintegration in the intestine than is the fiber of fruit or vegetable and is therefore more effective for counteracting constipation due to insufficient bulk. Good source of vitamin B and iron

GIRAFFE VACUUM PACKED FLORIDA
NATURAL ORANGE JUICE

Manufacturer—Tropical Juice Corporation of Florida, Miami and Titusville, Fla

Description—Canned orange juice, no added sugar or flavoring, retains in high degree the natural vitamin content

Manufacture—Tree ripened Florida oranges are washed, disinfected with borax or soda ash, rinsed, and stored in clean bins until used. The fruit is automatically halved. The juice is burred out by machine, the pressure being adjusted to avoid as far as possible extracting essential oil from the peel. The juice is strained through a series of screens, cooled to 4 C, processed at mild temperature, filled into containers which are sealed under reduced pressure (15 inches), processed at 71 C. for fifteen minutes, and cooled

<i>Analysis</i> (submitted by manufacturer) —	per cent
Moisture	87.0
Total solids	13.0
Ash	0.5
Fat (ether extract)	0.0

Calories—0.5 per gram 14 per ounce

Vitamins—Assay shows retention in high degree of vitamin C content

Claims of Manufacturer—Retains practically all the nutritive values of orange juice. For all dietary and table uses

VITAMIN D FORTIFIED HOMOGENIZED
PASTEURIZED MILK

Distributors—Babcock's Dairy Company, Port Huron, Mich. Alfalfa Creamery Company, West Palm Beach, Fla

Description—Bottled homogenized pasteurized milk fortified with vitamin D (vitamin D concentrate extracted from cod liver oil), contains 400 U S P X (Revised, 1934) vitamin D units per quart

Preparation—The milk complies with legal requirements and is homogenized and pasteurized by the standard holding method. See THE JOURNAL, July 1, 1933, page 34, for description of fortification with vitamin D

Vitamins—The vitamin D concentrate used and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent if the proper amount is used.

Claims of Distributors—A vitamin D fortified antirachitic homogenized pasteurized milk having otherwise the flavor and food values of usual homogenized pasteurized milk. The cream does not separate

AMERICAN LADY BRAND STRAINED BEETS CAR-
ROTS, CELERY, GREEN BEANS, PEAS, PRUNES
FLAVORED WITH LEMON JUICE, SPINACH
TOMATOES AND VEGETABLES WITH
CEREAL AND BEEF BROTH

UNSEASONED

Distributor—General Grocer Company, St. Louis

Packer—The Larsen Company, Green Bay, Wis

Description—Respectively sieved beets carrots celery, green beans, peas prunes flavored with lemon juice spinach, tomatoes and vegetables (carrots, potatoes tomatoes, celery peas, beans spinach) with pearl barley and beef extract, prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the respective accepted Larsen's vegetables and fruits (THE JOURNAL, July 1 1933, p 35, July 8, 1933, p 125 July 22 1933 p 282, July 29 1933, p 366, Aug 12 1933 p 525 Aug 19, 1933 p 605 Aug 26, 1933, p 675 Sept 2 1933, p 779)

DAVIDSON'S ANGEL FOOD CAKE

Manufacturer—Davidson Baking Company, Portland, Ore

Description—Angel food cake prepared from egg whites, sucrose, flour, cream of tartar, vanilla extract, sodium chloride and baking powder

Manufacture—The formula ingredients are worked into the egg whites in definite order. The batter is scaled, baked and cooled and the cake packed in cartons

<i>Analysis</i> (submitted by manufacturer) —	per cent

Packer—Vincennes Packing Corporation, Vincennes, Ind

Description—Pasteurized tomato juice with added salt retains in high degree the natural vitamin content. The same as Alice of Old Vincennes Tomato Juice (THE JOURNAL, Feb 20 1932, p 640)

PERFECTION FLOUR (BLEACHED)

Manufacturer—The Robinson Milling Company, Salina, Kan

Description—Hard winter wheat straight flour, bleached

Manufacture—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18 1932 page 2210. Chosen flour streams are blended and bleached with a mixture of benzoyl peroxide and calcium phosphate (14.2 Gm per barrel) and nitrogen trichloride (4 Gm per barrel)

PSYCHOLOGIC CONCOMITANTS OF PAIN

Pain in its various aspects offers an attractive field for study and speculation. According to Waterston¹ it is often, but not invariably, accompanied by other symptoms such as pallor, fainting and sweating, these are sometimes ascribed to the pain. They are not, however, invariable concomitants of pain and may hence be produced in a different way by afferent impulses other than those which cause pain traveling by a different path and producing their effects often by exciting the sympathetic system.

The psychologic concomitants of pain, Critchley² says, are manifold. An acute and severe pain usually dominates the victim's sensorium, often to the exclusion of other internal and external impressions. Inability to concentrate and irritability are of frequent occurrence during states of painful experience. The major affects of rage, fear, anxiety or despair may also accompany the feeling of pain. Their presence depends on the nature of the pain and the circumstances surrounding its production. Under the stress of an agonizing experience the sense of time may be disordered. This effect is commonly expressed as "each minute seemed an hour." Mental depression is, however, rare as a concomitant of severe pain. Thus, as Ribot puts it, "It seems as though the organism had but a limited capacity for either pleasure or pain and that neither feeling can exist at the same time in its double (physical and moral) form." Sleep may follow intense suffering, and in that which succeeds or accompanies the exhaustion of torture, dreams of a peculiarly vivid or complex character are often experienced. Jack London has described in *The Jacket* (the *Star Rover*) the particularly coherent and continuous visions of Durrell Standing while undergoing a series of ordeals by strait-jacket. "He would dream that he was addressing learned societies on abstruse problems, often waking to the sound of his voice ringing in his

ears and with imaginary pages of manuscript floating before his eyes, that he was journeying on horseback through the meadows of some vast farm, day by day the dream story would develop coherently and consecutively, and unroll itself before him. Shrubs and plants would grow from small beginnings into tall vegetation, which would later be felled by the laborers' axes, collected, dried and burnt in great heaps."

Accompanying the pain feeling—and even at times replacing it—there may be a stimulation of one of the special senses. In literary descriptions of painful experiences the language of some special sense is often used to describe the quality or intensity. Often it is in terms of color, and thus Homer refers to "black pains." In a minute analysis of this question Bleuler and Lehmann write "Pains are never felt or recollected without their appropriate colors. They are colored variously, according to their intensity. Violent pains are accompanied by an idea of white, still more intense pains go from yellow to red and to dark brown, dull headaches give a tint which is almost black, darting pains, an idea of white dots, a pinch, a yellow tint, which is clearer the keener the pain is, indigestion, a more or less clear gray, colic a clear yellowish tint, which may pass over the red or brown." This phenomenon may of course be reversed, as in the old lady in Kipling's "They," whom certain colors "hurt."

In spite of differences in subjective description, there does exist an obvious variation in the pain reactions of individuals to what is, as near as possible, an identical stimulus. Common experience teaches, Critchley states, that the burly, lymphatic artisan feels pain less than the fragile artist or thinker. As Mrs. Browning put it, "the mark of rank in nature is capacity for pain." Precise data in the matter are scanty, however, although MacDonald some years ago made a careful psychometric study of pain sensitivity. His observations confirmed the general impressions by demonstrating a greater sensitiveness in the young than in the old, and in women than in men. Such generalizations are dangerous, however, and it remains problematic how, for example, men would stand the pangs of childbirth.

Indifference and insensitivity to pain is a matter of great interest. A marked degree of indifference has been associated by Lombroso with habitual criminals. Occasionally persons are seen who seem to possess such a high threshold for nociceptive stimuli that pain rarely, if ever, enters their experience. One of the best examples of unusual insensitivity was E. H. Gibson, known in American vaudeville as "the human pincushion."

At times pain contributes a pleasurable sensation. In such instances it is often closely bound up with religion and has been associated with a subtle process of refining or cleansing whereby the individual is exalted. Self-infliction of pain may represent an effort to appease a sense of guilt or to atone for a misdeed. In

² Critchley, Macdonald. Some Aspects of Pain. *Brit. M. J.* 2: 891 (Nov. 17) 1934.

this connection the Biblical injunction is recalled "If thy right hand offend thee, cut it off and if thine eye offend thee, pluck it out" It is also possible that pain may be deliberately sought in order to relieve a more distressing discomfort or sensation Here the action appears to be counterirritant, but the exact limits at which it becomes a sign of insanity are hard to define

There are no words in English, Critchley says, to signify the state of mind that follows the cessation of a severe or protracted painful experience The resulting emotional state of relief is perhaps attended by definite, even if transient, physical and psychologic gratification Some psychologic concomitants of painful experience may linger after the pain has ceased Thus, as Hugh Walpole wrote in his novel *Hans Frost*, "I am suffering tonight from toothache, and I have always noticed that a toothache is the most unintellectual pain in one's body, just as, in all probability, a stomachache is the most intellectual Have you ever noticed, sir, how bright and clear one's brain becomes between the spasms of indigestion?" Many can, from their own experience, agree with one or both statements, but whether the clear headedness associated with some gastro-intestinal upsets is due to relief from pain or to starvation might well serve to inaugurate further investigation

RECENT ADVANCES IN THE STUDY OF GANGRENE OF THE EXTREMITIES

Experimental and clinical research into the etiology of gangrene of the extremities occupies an increasingly important place in modern medicine In this research the study of the larger vessels by morphologic methods has proved inadequate Thus Herrman and Reid¹ have concluded that neither arteriographic examination nor morphologic studies of the large vessels can furnish a satisfactory explanation of the clinical manifestations Rabinowitz² says "While an outstanding lesion in thrombo-angitis obliterans is a thrombotic closure of both large and small vessels, many clinical features of the disease cannot be attributed solely to this lesion" And now recent work by Popoff³ throws new light on the limitation and inadequacy of morphologic research confined mainly to the state of the large vessels of the extremities

In his studies on the digital vascular system, Popoff pays particular attention to the peripheral arteriovenous anastomosis in inflammation, arteriosclerotic gangrene, diabetic gangrene, obliterating thrombo-angitis and

supernumerary digits in man These arteriovenous anastomoses were discovered by Sucquet in 1862 and again by Hoyer in 1887, and they are recognized now as a normal constituent of the peripheral vascular system Popoff gives a detailed description of the anastomoses and discusses their function, which is controlled by local and general vasomotor mechanisms According to his description, peripheral arteriovenous anastomoses or, as he calls them, the digital glomus or digital glomic system, serve two functions, one local and the other general If the digits are exposed to cold it is through the agency of the glomic system that local temperature is maintained and even raised This is accomplished by diverting blood from the capillaries and rushing it through anastomoses into collecting veins with a highly developed surface area The glomic system also forms an important factor in the mechanism regulating the general temperature of the body When fully opened it aids the dispersal of heat by allowing an enormous flow of blood to pass through the digits The glomic system is not found in premature infants To this Popoff attributes their poor control of the temperature of the body No glomic system is found in cold blooded animals In man, with the advance of age, the glomic system undergoes atrophy and in old age it may disappear completely Comparative studies by Popoff on the glomic system in arteriosclerotic and diabetic gangrene indicate that in arteriosclerosis the destruction of the glomic system is due primarily to sclerosis of the afferent artery of the glomus, while in diabetes the arteriovenous anastomosis itself is involved first and this leads later to the destruction of the glomus In both cases functional incapacitation of the glomic system is sufficient to cause the trophic changes in these diseases Thus according to this concept the neurovascular and trophic changes in the digits of arteriosclerotic patients and persons with diabetes may be due primarily to changes in the glomic system and not to inflammatory, degenerative or obstructive changes in the large arteries

Popoff also offers a new concept of the etiology of obliterating thrombo-angitis In the cases of thrombo-angitis that he studied he found in the digits abnormal arteriovenous communications or anastomoses that are different from the normal arteriovenous anastomoses just discussed These abnormal anastomoses are found in the peripheral network of the digital vascular system By diverting blood directly and continuously into the veins they diminish seriously the amount flowing from the capillary bed As a result of this self-limited circulatory disturbance, the peripheral tissues of the digits suffer chronic and unrelievable anoxia with consequent development of the trophic changes and other manifestations characteristic of obliterating thrombo-angitis Both arteries and veins of the affected extremity undergo structural changes and, depending on the duration of the disease and the size of the abnormal arteriovenous anastomoses, the entire vas-

3 Popoff N W The Digital Vascular System with Reference to the State of the Glomus in Infection Arteriosclerotic Gangrene Diabetic Gangrene Thrombo-Angitis Obliterans and Supernumerary Digits in Man *Arch Path* 18 295 (Sept) 1934

cular system of the body may show signs of involvement. This concept of the centripetal spread of obliterating thrombo-angitis with the vascular anomaly as a causative agent is new and, if Popoff's results are corroborated, the nature of the disease will receive a new explanation.

THIRTIETH ANNIVERSARY OF THE COUNCIL ON PHARMACY AND CHEMISTRY

February 11, the Council on Pharmacy and Chemistry will complete its thirtieth year of service to the medical profession. For nearly a third of a century it has made contributions of inestimable value to rational therapeutics. Unique at its inception in 1905, it has no successful counterpart outside the United States. It has moreover served as a model for the Council on Physical Therapy and the Committee on Foods of the American Medical Association and for the Council on Dental Therapeutics of the American Dental Association.

Of the personnel of the Council, which serve entirely without remuneration, four members have been active ever since the meeting in Pittsburgh on Feb. 11, 1905, when the organization of this group was perfected. The secretary during the greater part of this period, W. A. Puckner, performed a notable service to medicine for twenty-seven years, until his death in 1932.

A comparison of the conditions prevailing in the marketing of drugs in this country before 1905 and those obtaining today indicates the debt that American medicine owes to the Council on Pharmacy and Chemistry. The rules governing the acceptance or rejection of remedies adopted in the beginning have gradually been amplified and clarified to meet new conditions. Thus the use of secret, ineffective and irrational preparations has decreased notably, advertising claims employed by manufacturers of pharmaceuticals for products accepted by the Council have attained standards of accuracy and truthfulness unequalled in any other field of marketing. *THE JOURNAL* and many other medical publications in this country, including the journals of all the state associations with the exception of Illinois, accept advertising for Council-accepted or official drugs only. But the Council's work would have come to naught had it not been for the militant aid of *THE JOURNAL* and the ever increasing support of the medical profession. True, many physicians still prescribe secret or semisecret or irrational preparations under the spell of persuasive, if unfounded, advertising claims made by certain manufacturers. But these clinicians are decreasing in number, more and more does the practitioner meet the claims of the detail man for a new pharmaceutical with the question "Is it accepted by the Council?"

Among the important contributions of the Council have been the evaluation of new drugs on the basis of available evidence, the publication of reports giving the

results of this evaluation, the standardization with the assistance of the A. M. A. Chemical Laboratory of products that show promise of therapeutic usefulness and the publication of special articles in review of subjects of current interest to the medical profession. A notable example of the latter is the series on Glandular Physiology and Therapy, which begins in the present issue of *THE JOURNAL*. In addition the Council issues several books: New and Nonofficial Remedies (revised yearly), Useful Drugs, the Epitome of the U. S. Pharmacopeia and National Formulary, and (in cooperation with the Council on Medical Education and Hospitals) Hospital Practice for Interns. It is impossible to present adequately, in so brief a compass, all the valuable services of the Council, which have made themselves felt wherever medicine is practiced throughout the civilized world. It continues its important tasks, ever increasing in number and volume, unselfishly and with intelligence and foresight. It merits unflinching support by the medical profession.

Current Comment

ASBESTOSIS

The nature of the effects of silica dust expressed in the term "silicosis," with the resultant extraordinary predisposition to pulmonary tuberculosis, is well known. Some of the more cogent etiologic, metabolic and legal aspects of this condition have been discussed in these columns.¹ These important developments in the study of lung diseases due to the inhalation of dust have now been extended in this country² to the pneumoconiosis caused by asbestos dust and termed "asbestosis." This preliminary study of the asbestos industry presents data obtained from an examination of dust conditions in five asbestos fabricating plants along the Atlantic seaboard. The investigation included physical examinations of asbestos workers, together with x-ray films, and a consideration of the dust exhaust systems designed to eliminate asbestos dust. It appears evident that prolonged exposure to this dust causes a pulmonary fibrosis demonstrable on x-ray films. This condition appears to be of a type different from silicosis and somewhat milder. Furthermore, a predisposition to tuberculosis due to asbestos dust was not indicated in this study. There were, however, cases of definite cardiac enlargement frequently associated with the asbestosis. The authors propose valuable recommendations, which include a thorough physical examination of prospective employees and suggestions for the control of dust hazards in the industry. Equally important is the proposal that the manufacturers sponsor studies of known cases of asbestosis as well as investigations on effects of the condition on the heart and the circulation. A more detailed report of the asbestos industry in the United States will undoubtedly provide further

WORKMEN'S COMPENSATION IN NEW YORK AND PENNSYLVANIA

Reports of committees on workmen's compensation in the states of New York and Pennsylvania respectively have recently been published.¹ These reports give an opportunity for judgment on a little more than twenty years' experience with workmen's compensation legislation in two large industrial states. The New York committee was composed entirely of physicians. The Pennsylvania committee contained two physicians out of seven members but also had an advisory committee of nine, seven of whom were physicians.

It is significant that in both cases the least satisfactory features of the operation of the law were in the provisions for medical care. It is fair to draw the conclusion from these reports that this weakness is largely due to the fact that there was little or no consultation with the medical profession at the time the laws were enacted. It is also worthy of note that among the more important recommendations of both committees is a wider participation of the medical profession in the administration of the provisions for medical care.

The New York committee subdivided the abuses in the operation of the law into "those over which the medical profession had at present no control and those directly attributable to the medical profession." Those which are beyond the control of the medical profession are listed as

- 1 The hiring of cheap and incompetent medical service by employers and insurance carriers
- 2 Reduced charges by hospitals in order to obtain cases
- 3 "Lifting"
- 4 Errors in causal relationship, where carriers have frequently attempted to prove wrongly that patients were malingering or where awards had been made by lay referees for conditions which had no relationship to the antecedent injury or occupation, or where a lay referee attempted to evaluate opposing medical testimony of experts employed by the interested parties
- 5 Postponement of compensation awards
- 6 Other legal injustices, most of which were also due to the control of the physician and medical records by an employer or an insurance carrier

Another set of abuses were ascribed to the medical profession. These are listed as

- 1 Inefficient medical treatment due to a failure to refer cases to a specialist when such treatment was needed
- 2 Overtreatment and overcharging
- 3 Prolonged period of compensation due to the fact that physicians have occasionally conspired with injured workmen to obtain compensation for him for a longer period than his injury warranted
- 4 Prolonged physical therapy
- 5 Inadequate medical testimony
- 6 Medical advertising and racketeering in order to secure cases

The committee submits a series of recommendations to remove these abuses. The first is a "limited free choice of physician by the employee." It is also recommended that opportunity be given for transfer of cases when this is found desirable and that the county medical society "function as the fact finding agency on professional conduct and professional competence."

Furthermore, it is recommended in the New York report that medical fees should be standardized by the medical society and arrangements made for the arbitration of disputed bills for medical service, medical practice by insurance carriers should be eliminated and there should be greater supervision of self insurers. The lay referees who are to determine disability

should have the right to avail themselves of expert medical opinion, and for this purpose a medical advisory and appeal board should be set up.

The Pennsylvania report is based on a very extensive study in which as many as 125 workers, paid through the CWA, investigated more than 7,000 workmen's compensation cases. There is a close resemblance between the medical recommendations of the committees in these two states. The Pennsylvania committee, however, urges that the present inadequate provisions for medical care of the Pennsylvania law be extended. It also urges at least a limited free choice of physician, wider opportunities for consultation and provision for impartial medical opinion.

This report contains an extensive and valuable graphic presentation of the features of the Pennsylvania compensation law in comparison with the laws of other states. There is considerable criticism of the self-insurance provisions of the law, although it is recognized that much of this criticism applies to only a minority of the self insurers.

Of the 7,000 cases studied, about "70 per cent of the persons interviewed expressed belief that they had received fair treatment. The others complained of delay, unfairness, and the necessity of litigation." They also complained of inadequate medical treatment and it was shown that more than two thirds were treated over a period of two months or longer and one fourth required medical treatment for four months or longer, although the law provides treatment for only thirty days.

It would seem to be a fair summary of the two reports to state that in the opinion of these committees, absence of medical advice in the formation of the law and dominance of lay interests, often seeking financial advantage, had defeated many of the purposes of the law, especially in regard to medical service. There is unanimous agreement that improvement in the medical service and in the other features of compensation which depend on that service must be based on a much wider participation of the medical profession and medical societies.

SPECIAL SESSION OF HOUSE OF DELEGATES AT CHICAGO, FEBRUARY 15

Reduced Railroad Rates for Return Tickets

Special rates have been granted by various passenger associations for the benefit of the members of the Annual Congress on Medical Education, Hospitals and Licensure and the Special Session of the House of Delegates in Chicago.

To have the benefit of a return rate of one-third fare, it will be necessary for each member to secure a Certificate from the railroad ticket agent when he purchases his ticket to Chicago. When the Certificate has been certified to and validated at the Palmer House in Chicago, it will entitle its holder to purchase a return ticket to his home, over the same route traveled to Chicago, at one-third fare.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles are as follows:

- | | |
|-------------|----------------------|
| February 14 | Heart Valves |
| February 21 | Heart Muscles |
| February 28 | Protecting the Heart |

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

- | | | |
|-------------|--|----------------------|
| February 12 | What the Public is Thinking About Health | W. W. Bauer M.D. |
| February 19 | Rheumatism and Gout | Morris Fishbein M.D. |
| February 26 | Health and Education | Morris Fishbein M.D. |

¹ Report of Governors Committee on Workmen's Compensation Pennsylvania Labor and Industry 31:4 (Nov.) 1934. Report of Committee on Workmen's Compensation appointed by Governor Herbert H. Lehman of New York.

Special Coast to Coast Broadcast

The American Medical Association will broadcast on a special program arranged through the courtesy of the National Broadcasting Company over a network of stations, beginning at 6 p m, eastern standard time Monday, February 18. The program will include music and three speakers from among physicians in attendance at the Annual Congress on Medical Education and Medical Licensure, meeting in Chicago on that day. The speakers will be introduced by Dr. Morris Fishbein. The speakers and their topics are as follows:

Advancement of Medical Education: Walter L. Biering, M.D.
The Prolongation of Life: Ray Lyman Wilbur, M.D.
The Battle Against Tuberculosis: Kendall Emerson, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bills Introduced—H 30 proposes to prohibit cities and towns of from 15,000 to 20,000 population from collecting occupational taxes on physicians practicing within their jurisdictions. S 26 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions.

ARIZONA

Bill Introduced—S 15 proposes to repeal the laws regulating the distribution and possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act.

ARKANSAS

Bill Passed—S 126 to supplement the medical practice act, has passed the senate, proposing that licentiates of the eclectic medical examining board shall register annually with that board and pay at that time a registration fee of \$2. Failure of an eclectic licentiate to register within the time stated is to suspend automatically his right to practice and a failure to register for three consecutive years shall automatically cancel his license to practice.

Bills Introduced—H 15 proposes to require any physician treating a person suffering from a gunshot pistol or bullet wound to report that fact immediately to the appropriate police authorities. H 105 apparently to supplement the pharmacy practice act proposes (1) to define drugs as any drug or compound listed in the United States Pharmacopeia or National Formulary, or both, which are [sic] used for the prevention, mitigation, or cure of disease; (2) to prohibit the distribution of drugs, as defined, except by registered pharmacies; (3) to permit the board of pharmacy to enjoin the operation of any store not complying with the pharmacy laws. H 110 and S 67 propose to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what the draftsmen of these bills cite as the uniform narcotic drug act. The bills, however, differ from the model uniform narcotic drug act in some important particulars and contain obvious errors in phraseology. They omit the provisions in the model bill intended to limit the gross quantity of a habit-forming drug a person can buy in exempt preparations within a period of forty-eight hours. S 142 proposes that all persons who have engaged in the practice of medicine for twenty years continuously prior to Jan. 1, 1935, shall, on presentation of such proof be entitled to registration by the eclectic medical examining board. H 82 proposes to provide compensation to workmen for injuries and occupational diseases or infections arising out of or in the course of their employment. The employer is to be required to furnish such medical, surgical and other attendance or treatment, nursing and hospital services, and medicines, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. Apparently the employer is to have the right to designate the physician and the hospital that are to treat or care for the injured employee. If the employer does not provide the services referred to after request by the employee, the employee may obtain them himself at the employer's expense. H 172 proposes to make it unlawful for a corporation to keep for its own benefit any unused portion of sums collected from its employees to provide them with medical services. It is to be

the duty of such a corporation to refund quarterly to its employees any accumulation of such funds not necessary to keep the medical service plan in operation. H 189 prohibits the sale of barbituric acid derivatives and/or compounds thereof except on the prescription of a licensed physician. S 107 proposes that all persons who have been engaged in the practice of medicine twenty years continuously prior to Jan. 1, 1935, on presentation of such proof be licensed by the homeopathic board, by the eclectic board or by the nonsectarian board of medical examiners, according to the applicant's school of practice.

CALIFORNIA

Special Meeting Called for House of Delegates—To formulate principles and policies on pending and proposed federal and state legislation related to medical care and medical services, a special meeting of the house of delegates of the California Medical Association has been called for March 2 in Los Angeles.

Bills Introduced—A 246 proposes to authorize the organization of corporations to provide on a nonprofit basis hospital care for their members and to exempt such corporations from the requirements of the state insurance law. The funds of a corporation organized under the provisions of this bill are to be exempt from all forms of state, county, municipal and school taxes. Such a corporation is specifically prohibited from in any manner providing medical service "in connection with the diagnosis or treatment of disease as controlled or prescribed by the medical practice act of the state of California or in any manner whatsoever engaging in the corporate practice of medicine and/or dentistry." A 255 proposes that the expert medical witnesses and the medical examiners whom the law permits a court to appoint to testify in a pending case shall be selected from a list of qualified physicians, prepared by the civil service commission after consultation with the state board of medical examiners, the medical director of the industrial accident commission, the deans of the medical schools of the University of California and of Stanford University, and the judicial council. A 429 proposes that every public and private school be so equipped as to render first medical aid to injured students. S 154 to amend the medical practice act, proposes (1) that a licentiate appealing from a judgment of the board of medical examiners revoking or suspending his license or placing him on probation must file with the clerk of the court a surety bond for \$250 to secure payment of the costs of appeal and (2) to make the following acts additional causes for the revocation or suspension of licenses: (a) fraudulent representation that a manifestly incurable condition can be cured, (b) advertising that the licentiate will treat syphilis or prostatic conditions or prostatic ailments, (c) the execution by a licentiate in his professional capacity of any false certificate, and (d) acceptance by a licentiate of employment from persons who directly or indirectly solicit patients. S 155 to amend the medical practice act, proposes to permit the issuance of a physician's and surgeon's certificate to an applicant who has completed three years' study in a medical school and has served at least one year's internship. S 311 to amend the laws regulating the sale, possession, distribution and use of narcotic drugs proposes that, in addition to any other penalty, any person convicted of unlawfully distributing narcotic drugs, who is not himself a drug addict, may be subject to from one to twenty lashes at a whipping post.

COLORADO

Annual Registration Due Before March 1—Every person licensed to practice any form of the healing art in Colorado is required by law to register annually before March 1, with the secretary-treasurer of the board of medical examiners and to pay a fee of \$2 if a resident of Colorado or \$10 if a non-resident. Failure to pay this fee within the time stated automatically suspends the right of a licentiate to practice while delinquent. If he nevertheless continues to practice he is subject to the penalties provided by law for practicing medicine without a license. Failure to pay this fee for three consecutive years results in the automatic cancellation of a delinquent practitioner's license to practice.

Bills Introduced—S 699 to amend the workmen's compensation act, proposes that if an employee or his representative is awarded compensation under the act no action may thereafter be brought against the physician who treated the industrial injury which was the basis of the award. S 700 proposes that every contract by which a hospital or a licensed practitioner of the healing art warrants or guarantees the specific result of treatment or care to be given any patient shall be void unless such contract or some note or memorandum thereof be in writ.

ing and be signed by the party sought to be charged therewith S 701 proposes that all actions for malpractice against a hospital must be instituted within two years after the accrual of the cause of action.

CONNECTICUT

Bill Introduced—H 28, to amend the chiropody practice act, proposes to define chiropody, or podiatry, as "the diagnosis of foot ailments and the practice of minor surgery upon the feet, limited to those structures of the foot superficial to the inner layer of the fascia of the foot, the dressing, padding and strapping of the feet, the making of plaster models of the feet and the palliative and mechanical treatment of functional disturbances of the feet as taught and practiced in the schools of chiropody recognized by the examining board

Lectures on Social Aspects of Medicine—The department of public health of Yale University School of Medicine is sponsoring a series of lectures in New Haven dealing with the backgrounds of medical practice. Dr Henry E Sigerist, director of the Institute of the History of Medicine, Johns Hopkins University, Baltimore, opened the series with three lectures on the development of medicine in relation to changing social conditions, January 14, 15 and 17. These lectures on the social aspects of medicine are designed especially for students of medicine but will also be open to the public. The department of public health has for some time been interested in furthering the investigation of the social backgrounds of disease in individual patients. According to an announcement the work has been developed under the direction of Ira V Hiscock, C.P.H., professor of public health, to the point at which a more comprehensive survey of the many aspects of American life as they pertain to health problems, is now thought desirable. The work on social backgrounds has been conducted with the cooperation of various agencies including the social agencies of New Haven, the city department of health, the social service department of the medical school and more recently the social science division of the Institute of Human Relations at Yale.

DELAWARE

Bill Introduced—H 38, to amend the workmen's compensation act, proposes to make compensable "any injury or disease arising out of and in the course of the employment as well as such disease or infection as naturally results directly therefrom when reasonably treated"

Society News—Dr Abraham Cantarow, Philadelphia, addressed the New Castle County Medical Society in Wilmington, January 10, on "Practical Aspects of Specific and Non-specific Calcium Therapy." Dr William H Speer, Wilmington, addressed the society, Dec. 18, 1934, on "The Injection Treatment of Varicose Veins"

ILLINOIS

Bills Introduced—H 96 proposes to impose a tax of 10 per cent of the gross cash receipts from sales in Illinois on persons manufacturing patent and proprietary medicines in the state. H 97 proposes to authorize the sexual sterilization of insane, feeble-minded mentally defective, idiot, imbecile or epileptic inmates of state institutions. H 44 proposes to repeal the laws regulating the distribution and possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act. H 109 proposes to accord liens to physicians and hospitals treating persons injured through the negligence of others, on all rights of actions, suits, claims or demands accruing to the injured persons because of their injuries.

District Meeting—The Iowa and Illinois Central District Medical Association held its quarterly meeting at the Blackhawk Hotel in Davenport, Iowa, January 11. The president, Dr John C Souders, Rock Island, gave a tribute to Dr George L. Eyster, who practiced medicine in the community for fifty-five years and who now lives in Coral Gables, Fla. Other speakers were Drs Merrill M Benfer, Davenport, on 'Consideration in the Treatment of Hypertrophied Prostate'; William H Olmstead, St Louis, 'Vascular Diseases of the Extremities'; and Louis G Herrmann, Cincinnati, 'Recent Advances in the Treatment of Obliterative Arterial Diseases of the Extremities'. Several patients with arterial disease of the extremities were presented at this meeting.

Chicago

Malaria Among Narcotic Addicts—The use of the same syringe by several narcotic addicts was said to be the cause of an outbreak of malaria recently. Five deaths from the disease in the county hospital prompted a raid on the hotel where two

of the victims lived. Two of the men arrested were found to be potential malaria carriers, having had the disease several years ago. They confessed to being part of a group of addicts that usually met together and used the same syringe.

Society News—A symposium on transurethral resection constituted the program of the Chicago Urological Society, January 24, speakers were Drs Edward W White, Harry Culver, Herman L Kretschmer and Irvin S Koll.—Dr Royd R Sayers of the U S Public Health Service, Washington, D C, discussed "Silicosis as a Factor in Compensation and Personal Injury Cases" at a meeting, January 26, sponsored by the hospitality committee of the Chicago Bar Association. Members of the Chicago Medical Society and the Chicago Society of Industrial Medicine and Surgery were invited.—The Chicago Medical Society held a memorial meeting, January 27, in honor of its members who have died in the past year. In addition to a musical program, Dr William Allen Pusey discussed "Medicine the Last Fifty Years and the Next Fifty," and Frederick F Shannon, pastor of the Central Church, "Some Doctors I Have Known".—Dr George W Crile, Cleveland, addressed the Public Affairs Round Table of the Union League Club of Chicago, January 25, on "Medical Research, Health and Longevity." This lecture accompanied the first showing of the sound motion picture "That Man May Live," prepared by the American College of Surgeons.

INDIANA

Bills Introduced—H 113 proposes to authorize the state board of pharmacy to appoint a narcotic inspector to enforce, and to collect information necessary to enforce, the state and federal laws relating to narcotic drugs. S 83 proposes to repeal the laws regulating the distribution and possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act. S 118, to amend the workmen's compensation act, proposes (1) to make occupational diseases compensable, and (2) that no physician be permitted to testify at any hearing provided for in the act or in any action at law brought against an employer who is subject to the act, unless, at the time of making his report to the party employing him, he shall also furnish the opposite party with a copy of the report, setting out in detail the history, complaints and findings. H 211 proposes to authorize counties, cities and towns to supply insulin free of charge to citizens who are in need of insulin treatment for diabetes and who are financially unable to purchase the drug.

IOWA

Bill Introduced—S 20 proposes that before any applicant for a license to practice medicine, osteopathy, osteopathy and surgery or chiropractic may be examined by his professional board he must first pass an examination before an impartial basic science board in anatomy, physiology, chemistry, pathology, bacteriology and hygiene. The basic science examining board is to consist of five members of the faculties of the State University, the State College of Agriculture and Mechanic Arts, the Iowa State Teachers College and any other university or college accredited by the Iowa state board of educational examiners. All members of the board must be learned in the basic sciences and no member may be licensed to practice any of the healing arts.

LOUISIANA

Centennial Celebration at Tulane—The one hundredth anniversary of the establishment of Tulane University of Louisiana School of Medicine, New Orleans, was commemorated in a program sponsored by the Orleans Parish Medical Society, January 7. This observance is a forerunner of the celebration planned by the university in June for three or four days, culminating on commencement day, June 12. The recent program marked the actual day of its founding the first Monday in January 1835. The history of the institution was reviewed by Mayor T Semmes Walmsley, and Drs Charles C Bass, dean, Waldemar R. Metz, Albert E Fossier and Rudolph Matas.

MARYLAND

Bills Introduced—H 36, to amend the workmen's compensation act, proposes to eliminate those provisions in the present law which define the evidence that must be submitted in order to permit recovery of compensation for hernia. H 53 proposes to require both parties to prospective marriages, as a condition precedent to obtaining licenses to wed, to present certificates from licensed physicians that both parties are free from contagious disease.

MASSACHUSETTS

Personal—Dr Edward B. Lane, Boston, has resigned as medical superintendent of an institution for mild nervous disorders, after twenty-five years' service. He has been succeeded by Dr James Martin Woodall.—Dr James B. Atwater, Westfield, resigned as chief of staff of the Noble Hospital, Nov. 24, 1934, after twenty-seven years' service, he was made chief emeritus and Dr Edward S. Smith was appointed to succeed him.

Bills Introduced—H 358 proposes to authorize the department of mental diseases to construct a hospital for drug addicts on Rainsford Island, in the city of Boston. H 1736 proposes to prohibit the distribution of any article intended as a sex inciting device or contrivance and to prohibit the distribution, except by physicians or pharmacists, of any article intended to be used for the prevention of venereal disease. H 1400 proposes a system of compulsory and voluntary sickness insurance. The benefits proposed consist of cash and all forms of medical and dental service. Persons employed at "other than manual labor" and receiving wages in excess of \$60 a week, farm laborers and persons employed by an employer having less than three employees in personal or domestic services, are excluded from the compulsory insurance of the bill but are entitled to participate in the voluntary insurance.

MICHIGAN

Bill Introduced—H 92, to amend the workmen's compensation act, proposes to make compensable all disabilities or death suffered by an employee as a result of occupational injury or disease.

Detroit Health Council—The creation of a Metropolitan Detroit Health Council to secure good health service for all the people at a minimum of expense was unanimously endorsed at a meeting of the Wayne County Medical Society, Dec. 17, 1934. It was recommended that the officers of the society be empowered to effect this organization in cooperation with community agencies dealing with medical service and health protection. About 400 members of the society attended the meeting. Following a discussion of medical economics, William J. Burns, executive secretary of the society, outlined the plans for the organization of the health council, and Dr Charles Godwin Jennings introduced the resolution that recommended its creation.

MINNESOTA

Lectures for Teachers' Colleges—The Minnesota State Medical Association, cooperating with the Minnesota Public Health Association, is providing a health lecture course for the teachers colleges of the state. The course consists of a series of five lectures, one each month, by prominent physicians of the state. The titles of the lectures are Milestones of Medicine, Youth's Greatest Enemy, That Heart of Yours, Heritage of Health, and Your Senses and You.

Bills Introduced—H 86 proposes to authorize the sexual sterilization of inmates of state institutions who are afflicted with mental deficiency, perversion, marked departures from normal mentality or from disease of a syphilitic nature, likely to be transmitted to descendants. S 145 proposes to amend the law prohibiting the procuring of an abortion or miscarriage. The present law permits the use of any means to procure a miscarriage if "the same is necessary to preserve" the life of the woman. This bill proposes to permit also the procuring of a miscarriage if it is necessary to preserve the life of the fetus. S 177 proposes to provide for the licensing of dental hygienists by the board of dental examiners. A dental hygienist is to be authorized to remove lime deposits, accretions and stains from the exposed surfaces of the teeth, administer gas, ether and general anesthesia, and to make instrumental examination of the teeth or cavities. A dental hygienist, however, must operate (1) in the office of a licensed dentist and at all times under his direct supervision or (2) in a public institution or school if at all times under the general supervision of a licensed dentist. H 212 proposes to require every physician or the governing authorities of every hospital, on treating persons suffering from gunshot or knife wounds, to report the facts immediately to the proper police officials.

MISSOURI

Physical Therapy Committee Appointed—At the annual meeting of the council of the Missouri Medical Association in Columbia, Nov. 19, 1934, the organization of a committee on physical therapy was approved. Drs Alexander J. Kotkis and Frank H. Everhardt, St. Louis, were named members of the committee, with three other members to be appointed later.

Bills Introduced—S 28 proposes to make it unlawful for any person to cultivate, cure, prepare, distribute in any manner or possess marijuana. Physicians, dentists and osteopaths, however, are to be permitted to prescribe marijuana. H 14, to amend the workmen's compensation act, proposes, in effect, to permit chiropractors and osteopaths to render the medical and surgical treatment called for in that act.

MONTANA

Bill Passed—S 35, to supplement the pharmacy practice act, has passed the house, proposing to authorize the state board of pharmacy to adopt rules requiring registered pharmacists to keep a record of all poisons sold or disposed of, containing the signatures of the purchasers and such other information as may be required by the board.

Bill Introduced—H 86, to amend the chiropractic practice act, proposes (1) to define chiropractic as "the science that teaches that disease results from anatomic disrelation and teaches the art of restoring anatomic relation by adjustment by hand and the use of such other physical, thermal and electrical methods and modalities as are necessary to the restoration of proper anatomic relation," and (2) to require a chiropractic licensee to show as a condition precedent to his right to annual reregistration that during the past year he has attended a postgraduate course in a recognized chiropractic college or has attended at least one of the "educational" programs as conducted by the Montana chiropractic association.

NEBRASKA

Bills Introduced—H 143 proposes to make it the duty of every physician, hospital or pharmacy treating any person suffering from any injury inflicted by a knife, gun, pistol or other deadly weapon, or by other means of violence, to report immediately to the appropriate police officials the name and address of the patient and the nature and extent of the injuries. S 50, to amend the optometry practice act, proposes, among other things, to define optometry as "the science of diagnosing disturbances of the visual apparatus and functions." H 137 and H 147 propose to repeal the laws regulating the distribution and possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act. H 230 proposes a system of compulsory and voluntary sickness insurance. The benefits proposed consist of cash and of all forms of medical and dental services. Persons employed at "other than manual labor" receiving wages in excess of \$250 monthly, farm laborers, and persons employed by an employer having less than three employees in personal or domestic services, are excluded from the compulsory insurance of the bill but are entitled to participate in its voluntary insurance.

NEW HAMPSHIRE

Bills Introduced—H 143 proposes to make it the duty of pension act, among other things proposes to require the employer to furnish to an injured employee, without limit as to time or amount, reasonable medical and hospital services and other remedial care. H 196 proposes to limit the administration of anesthetics to licensed physicians and dentists. It proposes also to prohibit the administering of an anesthetic unless a responsible adult third person is present at the administration and during the period the patient is under the anesthetic. H 270, to amend the chiropody practice act, proposes to define a chiropodist as "one who examines, diagnoses, or treats medically, mechanically, surgically, or by electrical and manipulative means, or by bandaging and strapping, the ailments of the human foot not requiring the use of anesthetics other than local." H 153 proposes to accord to hospitals, caring for persons injured through the fault of others, items on all rights of action, claims judgments, settlements or compromises accruing to the injured persons by reason of their injuries.

NEW JERSEY

Bill Introduced—S 50 proposes to authorize the sexual sterilization of idiot, epileptic, imbecile and feeble-minded inmates of state institutions.

Surgeons' Annual Meeting—Dr. Briscoe B. Ranson Jr., Maplewood, was elected president of the Society of Surgeons of New Jersey at Newark, January 9. Speakers included

- Dr. George W. Crile, Cleveland, The Adrenal Sympathetic System and Its Diseases
- Dr. Arthur H. Curtis, Chicago, Obstructive Lesions of the Uterus and Their Complications
- Dr. Walter E. Dandy, Baltimore, Diagnosis and Treatment of Disturbances of the Cranial Nerves
- Dr. Philip D. Wilson, New York, Injuries in the Region of the Elbow
- Dr. Henry Bugbee, New York, Present Status of the Prostatic Problem
- Dr. William Wayne Babcock, Philadelphia, Management of Carcinoma of the Large Bowel

NEW MEXICO

Bill Passed—H 57 has passed the house, proposing to require the board of pharmacy to license, without examination, any licensed physician who owns or operates a drug store or any other business requiring the services of a registered pharmacist

NEW YORK

Bills Introduced—S 401 proposes to prohibit the advertisement, display, sale or other disposal of appliances, drugs or medicinal preparations intended or having special utility for the prevention of venereal disease and/or used in gynecologic hygiene or treatments, except in places duly registered by the state board of pharmacy S 357 and H 445 propose to safeguard the distribution of "dangerous caustic or corrosive substances," as defined in the Federal Caustic Poison Act, by requiring their labeling as poison S 344 proposes to amend that provision in the vital statistics law which requires that the personal particulars called for in a certificate of birth shall be authenticated by the signature of an informant, who may be any competent person acquainted with the facts, by providing that such personal particulars shall be obtained from such a person. A 461, to amend the medical practice act, proposes to make it unlawful for any one other than a licensed physician to conduct, direct, supervise or control the work or reports of a clinical laboratory, which is defined as "a laboratory in which tests are made on individual persons, their secretions, excretions, blood and tissues, to aid in the diagnosis, prognosis, or treatment of the individual's physical or mental state or states" The provisions of this bill, however, are not to apply to qualitative or quantitative analysis of urine by a licensed pharmacist, or to a clinical laboratory director duly licensed to conduct, direct or supervise a clinical laboratory within the city of New York or to any person who has conducted, directed or supervised a clinical laboratory in the state for a period of at least six months prior to the date this bill may become enacted. S 409 and A 551 propose that that portion of a street in front of a physician's residence, if properly marked, shall at all times be reserved as a parking space for the physician's personal use and for the use of persons visiting him professionally A 558 proposes to prohibit the employment of nurses by state, county or city hospitals or in hospitals supported in whole or in part by public funds, for more than eight hours in any one day

New York City

Laboratory Service on Pneumonia.—The bureau of laboratories of the department of health has recently extended its diagnostic service for the typing of pneumococci by opening a branch laboratory for that purpose at Bellevue Hospital

Study of Amebic Dysentery.—The U S Public Health Service reports a study of the occurrence of amebic dysentery in New York between Nov 1, 1933 and Sept 30 1934 Before October 1933 dysentery was rarely reported in the city, only nineteen, twenty and twenty cases having been listed in 1930, 1931 and 1932 When a warning was received from the Chicago health department that an outbreak had occurred in that city, intensive studies were begun of all cases reported to the New York health department Of 121 cases that occurred between Nov 1, 1933, and Sept 30 1934 seventy-three, or 60.3 per cent, originated in Chicago Of the remaining cases, thirteen apparently originated in New York, fifteen in places in the United States outside of Chicago and New York and twelve in foreign countries In eight instances the source of infection could not be traced At the end of the period studied seventeen deaths had occurred, forty-one patients were said to have recovered and sixty-three were still undergoing treatment The largest number of cases, twenty-seven, was reported in December 1933 The number of cases reported from January to September 1934 thirty two attributed to sources other than Chicago affords a better indication of the normal incidence of dysentery in the city the report concludes Of the usual number a fairly constant percentage comes from foreign sources The apparent increase over earlier years may be ascribed to greater interest or increased diagnostic skill on the part of physicians or to better reporting, it is noted

NORTH DAKOTA

Bill Introduced—H 73 proposes to create a board of naturopathic examiners and to regulate the practice of naturopathy According to the bill naturopathy, which includes physiotherapy, is defined to be "The treating of the human body for hygienic [sic] or remedial purposes by means of massage, baths heat, light vibration, manipulation, nontoxic herbs and diet as taught by Naturopathic Schools and Colleges"

OHIO

Columbus Credit Bureau—The Columbus Academy of Medicine has authorized the establishment of a credit bureau to be known as the Columbus Bureau of Medical Economics, through which patients' credit ratings will be recorded and exchanged, and delinquent accounts will be handled Dr Eugene F McCampbell has been named president and Dr Russel G Means, secretary

Personal—Dr Gustav Eckstein Jr, Cincinnati, author of several novels and of "Noguchi," received the Sachs Prize of \$500, given annually to a Cincinnati who has made a notable contribution to art, literature, science or education.—Dr and Mrs Florus Fremont Lawrence, Columbus, celebrated their golden wedding anniversary, January 1 Dr Lawrence was professor of surgery, anatomy and clinical surgery at the old Ohio Medical University, clinical lecturer in abdominal pelvic surgery at Starling Medical College, and in later years, 1906-1916, clinical lecturer on surgery at Ohio State University College of Medicine In recent years he has been on the staffs of McKinley and White Cross hospitals He is a former president of the Columbus Academy of Medicine.

OKLAHOMA

Bills Introduced—H 126 proposes to create a board of chiropody examiners and to regulate the practice of chiropody which the bill defines as the examination, diagnosis or treatment manually, mechanically, medically or surgically of the ailments of the human foot except the amputation of a toe or foot, and the use of anesthetics other than local H 101 proposes to amend the laws relating to divorce by permitting a divorce when either spouse has been adjudicated insane and has been confined in an institution for treatment for three years or more

OREGON

Bills Introduced—H 57, to amend the laws relating to taxation, proposes to deny exemption from taxation to any incorporated hospital which makes a charge for its services on the ground that such a hospital is a noncharitable institution H 85 proposes to repeal the law requiring applicants for marriage licenses to present medical certificates showing their freedom from venereal and certain other communicable diseases and certain inheritable diseases and conditions

Bill Passed—H 112, to amend the medical practice act, has passed the house It proposes (1) to permit the medical examining board to hold meetings for examinations whenever it deems them advisable, provided such meetings are held at least twice each year, the present law requiring that meetings for examination be held on the first Tuesdays of January and July, (2) to permit the board to suspend licenses as well as to refuse to issue or to revoke them for the causes now stated in the law, and (3) to add to the conduct which shall be deemed to be "unprofessional or dishonorable conduct" "the obtaining of any fee through fraud or misrepresentation"

PENNSYLVANIA

Survey of Maternal Health—The Medical Society of the State of Pennsylvania through its commission on maternal welfare is undertaking a complete survey of the problem in the state Dr James S Taylor, Altoona, chairman of the commission, has asked each county society to appoint a local committee whose chairman will become a member of the councilor district committee and the chairman of the district will in turn be a member of the commission

Bills Introduced.—H 187 proposes an amendment to the constitution to permit the general assembly to establish a system of compulsory health insurance H 188 proposes to establish a system of compulsory health insurance in favor of all persons engaged in manual labor and all other employed persons earning \$50 a month or less The proposed benefits, in case of illness or accident, consist of necessary medical, surgical, dental, nursing and hospital attendance and treatment, available alike to the employed person and to the dependent members of his family H 271 proposes to authorize the establishment of a state tuberculosis sanatorium in one of the state forest reservations

Philadelphia

Neurologic Society Fifty Years Old—The Philadelphia Neurological Society celebrated its fiftieth anniversary, January 22 with a meeting at the headquarters of the College of Physicians of Philadelphia Dr William G Spiller read a paper on "Fifty Years of Psychiatry," and Dr Charles H Frazier one on "Neurosurgical Activities of Members of the Philadelphia Neurological Society"

Bequest to Pennsylvania Hospital—Mrs Henrietta Dallas Pepper, a great-great-granddaughter of Benjamin Franklin, left the greater part of her \$200,000 estate to the Pennsylvania Hospital to establish a ward "for persons of gentle birth but unable to pay," according to newspaper reports. The ward is to be a memorial to her husband, John W. Pepper, who died in 1918. Mrs Pepper died, Dec. 23, 1934.

Pittsburgh

Travel Club Meeting—The Obstetrical and Gynecological Travel Club including physicians from Montreal, Boston, New York, Philadelphia, Chicago, Rochester (Minn.) and Washington, D. C., held its annual meeting in Pittsburgh, Dec. 2-4, 1934. Clinics were presented at various hospitals by the following Pittsburgh physicians: Drs. Charles H. Aufhammer, Charles J. Barone, Bender Z. Cashman, Sidney A. Chalfant, Josiah R. Eisaman, Thomas Evans Jr., Raymond A. D. Gillis, James L. Gilmore, Raleigh R. Huggins, David B. Ludwig, Thomas K. Reeves and Paul Titus. Among social features were a buffet supper at the home of Dr. Titus and a dinner at the University Club at which Dr. Frederick C. Irving, Boston, read a paper on toxemias of pregnancy.

TENNESSEE

Bills Introduced—H. 204 to amend the chiropractic practice act, proposes (1) that the membership of the board of chiropractic examiners be increased from three to five, (2) that the board be appointed by the governor from a list of names submitted by the Tennessee Chiropractic Association, and (3) to provide staggered terms of three years for board members. H. 265 and S. 168 propose, among other things, to impose an annual occupational tax on physicians equal to 1 per cent of the gross income derived from the practice of their profession.

Bill Enacted—S. 97 has become a law, providing that the board of health shall consist of nine members appointed by the governor, of whom six shall be licensed practitioners of medicine, one a licensed dentist, one a licensed pharmacist and one a member of the Tennessee congress of parents and teachers and the Tennessee Federation of Women's Clubs. The medical members are to be appointed from a list of names submitted by the Tennessee State Medical Association. The board is to formulate the policies and supervise the activities of the department of public health.

TEXAS

Bills Introduced—S. 59 and H. 107 propose to authorize the sexual sterilization of mentally defective, deficient or diseased inmates of state institutions.

Gastro-Enterologists Organize—The Texas Society of Gastro-Enterologists was organized, Nov. 16, 1934, during the meeting of the Southern Medical Association in San Antonio. Dr. Harry G. Walcott, Dallas, was elected president and Dr. Franklin D. Garrett, El Paso, secretary. The next meeting will be in connection with the annual session of the Texas State Medical Association in Dallas in May.

UTAH

Bill Introduced—H. 4, to amend the workmen's compensation act, among other things proposes to make compensable any "disease which is the result of the occupation or employment."

WASHINGTON

Bills Introduced—S. 14 proposes to authorize the establishment of a hospital for the treatment of drug addicts and to provide a procedure for the commitment of drug addicts to it. The bill defines a "drug addict" as one "who unlawfully administers to himself or unlawfully has administered to himself by others any habit-forming narcotic drug." S. 32 proposes to eliminate from the criminal code those provisions prohibiting the possession, sale or other distribution, or the use, of contraceptives. H. 28 proposes to accord to physicians, nurses and hospitals, treating persons injured through the negligence of others, liens on all rights of action, claims, judgments, compromises or settlements accruing to the injured persons by reason of their injuries.

WISCONSIN

Bill Introduced—A. 70 proposes to require every physician or midwife attending a confinement case to instil a 1 per cent solution of silver nitrate into the eyes of the baby immediately after its birth.

Two Positions for Women Physicians—The state bureau of personnel announces that two vacancies are anticipated in the

state board of health, for which women physicians are invited to apply: supervisor of the maternity and child welfare division, a permanent position, and maternity and child welfare physician, a position that will last about ten months, during a leave of absence of the present incumbent. Minimum qualifications are training equivalent to that represented by graduation from a medical school of recognized standing, a license or eligibility for a license to practice in Wisconsin, five years of practice with special experience in pediatrics and public health, ability as a public speaker, endurance, and good physical condition. Out of state candidates who are citizens of the United States will be accepted for both positions. Photographs and medical certificates must accompany applications which must be filed before February 15. Blanks may be obtained from the bureau of personnel, Madison.

WYOMING

Bill Introduced—S. 47 proposes to authorize any school district to employ a licensed physician to care for and treat school children.

GENERAL

License Missing—Dr. Lewis Robert Wolberg, Kings Park, Long Island, N. Y., recently reported to the California State Board of Medical Examiners the disappearance of his license to practice medicine in California.

Association Favors New Food and Drug Legislation—The American Association for the Advancement of Science at its meeting in Pittsburgh, Dec. 31, 1934, adopted a resolution supporting revision of the Food and Drugs Act. The statement expressed the conviction that cosmetics should be included in any new bill presented and that manufacturers, their salesmen or other agents, should be allowed to use in their advertising, printed, broadcast or otherwise presented, only such statements as are not misleading and are essentially in accordance with fact.

Orthopedists Form Examining Board—At the annual session of the American Academy of Orthopedic Surgeons in New York, January 15-17, 1934, the American Board of Orthopedic Surgeons was organized to certify qualifications of physicians who wish to specialize in that field. Dr. Melvin S. Henderson, Rochester, Minn., was named chairman, and other members include Drs. Fremont A. Chandler, Edwin W. Ryerson and Philip Lewin, Chicago; Henry W. Meyerding, Rochester, Minn.; William Barnett Owen, Louisville, Ky.; John C. Wilson, Los Angeles; Hulett J. Wickoff, Seattle; and Samuel Klemberg, New York. Dr. Henderson was also chosen president elect of the academy and Dr. Frank D. Dickson, Kansas City, Mo., was installed as president. Dr. Lionel D. Prince, San Francisco, was elected vice president and Dr. Philip Lewin, Chicago, reelected secretary.

Lea and Febiger Publish Memorial Volume—In recognition of 150 years of publishing, Lea and Febiger have just made available a sketch originally prepared by Mr. Henry Charles Lea in 1885 to celebrate the one hundredth anniversary of the founding of that business, revised and amplified to bring it up to date. The volume is beautifully illustrated with facsimiles of letters and with some fine portraits. This company has been operated continuously by members of the same family. The first editor of the *Philadelphia Journal of the Medical and Physical Sciences* established in 1820, later the *American Journal of the Medical Sciences* was Nathaniel Chapman, also the first president of the American Medical Association. The publication became the *American Journal of the Medical Sciences* in 1827, under the editorship of Dr. Isaac Hays, who was also in charge of the committee that prepared the *Principles of Ethics of the American Medical Association*. The company takes particular pride in its continuous publication in America of Gray's *Anatomy*, beginning with 1859.

Annual Report of Commonwealth Fund—Fifty-eight per cent of the \$1,720,514.54 expended by the Commonwealth Fund in the year ended Sept. 30, 1934, was devoted to public health, rural hospitals, medical education and medical research, according to the annual report issued January 14. During the year the fund helped to finance a community hospital in Kingsport, Tenn., in the region served by the Tennessee Valley Authority, similar to the six community hospitals it has supported in the past few years. In the latter hospitals, average occupancy increased 22 per cent over the previous year. The collections on patients' accounts increased 33 per cent. The fund has aided rural health agencies in Massachusetts, Mississippi and Tennessee. In Mississippi a special epidemiologic unit has been in operation. During the past few years 272 scholarships for graduate medical work have been given to physicians.

The fund is now subsidizing experiments at the Boston Children's Hospital and the New York Babies Hospital, in which students of pediatrics may observe psychiatric and psychologic methods of handling children. Support of the Child Guidance Clinic in London is being continued. Medical research sponsored by this foundation included a study of tuberculosis in the infant and preschool child at Johns Hopkins University School of Medicine, of placental extract at Harvard Medical School, and of serum treatment of pneumonia under the direction of the Massachusetts State Department of Health.

Medical Bills in Congress—Changes in Status S 1226 has passed the Senate, proposing to prohibit the sending of unsolicited merchandise through the mails. S 1175 has passed the Senate and House, extending the functions of the Reconstruction Finance Corporation for two years. The House rejected an amendment that would have authorized loans to colleges, universities and institutions of learning, and to hospitals. **Bills Introduced** S 337, introduced by Senator Vandenberg, Michigan, proposes to furnish to certain seamen hospitalization and medical treatment at hospitals and relief stations of the United States Public Health Service. S 1375, introduced by Senator Copeland, New York, proposes to amend the penal laws of the United States so as to authorize the importation into the United States, and the interstate transmission by any express company or other common carrier, of books or information relating to the prevention of conception, or articles, instruments, substances, drugs, medicines, or things designed, adapted, or intended solely for the prevention of conception, if (1) for use by any physician legally licensed to practice medicine, or by his direction or prescription, (2) for use by any druggist in filling any prescription of any such licensed physician, (3) for use by any medical college legally chartered under the laws of the United States or of any state or territory, or of the District of Columbia, or (4) for use by any hospital or clinic chartered under the laws of the United States or licensed under the laws of any state or of any territory, or of the District of Columbia. H J Res 8, introduced by Representative Bland, Virginia, would authorize Hugh S. Cumming, Surgeon General John D. Long, Medical Director, and Clifford R. Eskey, surgeon, all of the United States Public Health Service, to accept certain decorations bestowed on them by the governments of Ecuador, Chile and Cuba. H R 25, introduced by Representative Huddleston, Alabama, proposes to authorize the Bureau of Standards to adopt and prescribe grades and standards of quality of objects of commerce and to adopt and prescribe marks and symbols and/or figures indicating such grades and standards, and to adopt regulations for the use of such marks, symbols and figures as indicating quality, grade or standard. H R 2061, introduced (by request) by Representative Knutson, Minnesota, proposes to revise the laws and regulations relating to pensions and other allowances for veterans and their dependents. H R 3039 introduced by Representative McSwain, South Carolina, proposes to authorize the acquisition of additional land for the use of the Walter Reed General Hospital. H R 4317, introduced (by request) by Representative Zioncheck, Washington, proposes to incorporate the American White Cross Association on Drug Addiction. H R 4513, introduced by Representative Kopplemann, Connecticut, proposes to authorize the payment of claims for unauthorized emergency treatment of World War veterans. H R 4871, introduced by Representative Pearson, Tennessee, proposes to authorize the Reconstruction Finance Corporation to make loans to institutions of learning, and to hospitals. H R 5055, introduced by Representative Dockweiler, California, proposes to provide for the rehabilitation of and uniform pensions for, all totally blind soldiers of the Army, Navy and Marine Corps and war nurses

are on the waiting list for examination. This work is financed by federal and state funds from various sources, with impetus from funds provided by the Agricultural Adjustment Administration.

Internship Available at St. Elizabeth's

The U S Civil Service Commission has announced a competitive examination for junior medical officer (intern) at St. Elizabeth's Hospital, Washington, D C, for which applications must be on file not later than February 18. Two types of internship are offered. The first type is a two year internship consisting of a rotating service of four months each of surgery, acute medical service and chronic medical service, six weeks each of obstetrics and pediatrics (affiliation), three months of general laboratory work, and six months of psychiatry. The second type is a graduate internship of one year in psychiatry, for which physicians who have already had an accredited internship are desired, although applications will be accepted from those who have not. Applications will be accepted from fourth year students in medical schools that require a year of internship before granting a degree, as senior students to serve the intern year, and from senior students in other schools subject to their furnishing proof of graduation during the existence of the eligible register. Full information may be obtained from the secretary of the U S Civil Service Board at the postoffice or customhouse in any city that has a postoffice of the first or second class or from the Civil Service Commission, Washington, D C.

Annual Report on Health of Army

For the first time in the U S Army, injuries from athletics lead the causes of admission to sick report with a rate of 28.4 per thousand, according to the annual report of the surgeon general for 1933. The lowest admission rate (578.5) ever achieved was recorded for this year, while a new low rate (34.4 per thousand) was indicated for venereal disease incidence as compared with 42 for the previous year. The total army had an average daily strength of 136,491 during the year, an increase of 4,566 over that of the previous year. The percentage of first enlistments of the total number enlisted was 38.2 which was higher than the two previous years (25.5 and 29.8) but lower than the rate of 43.6 for 1930. The total number of days spent in the hospital during the year was 1,355,245. In addition there were 1,008,140 hospital days chargeable to beneficiaries of the Veterans' Administration, soldiers' homes, members of the national guard, officers' reserve corps, reserve officers training corps, citizens military training camps, civilian conservation corps and civilians entitled to medical treatment. This totals 2,363,385 hospital days as compared with a total of 2,425,343 days spent in hospital during 1932. In addition there was an average of 395 patients each day treated in quarters and 1,290,142 outpatients treated. There were 686,327 physical examinations performed and 949,966 vaccinations of various kinds administered. For the fiscal year 1934 the per diem cost of hospitalization in army hospitals was \$4.60. The number of Veterans Administration beneficiaries was materially reduced but this was offset by the influx of civilian conservation corps patients. The admission rate for officers (487) was the lowest for the past decade. There were 577 deaths during 1933, as compared with 567 in 1932 and 626 during 1931. Excluding three of these deaths, which were among nurses, the death rate for the whole army was 4.2 per thousand, as compared with 4.3 the previous year. Automobile accidents headed the list as the most important cause of death, as they have since 1930. During 1933 there were seven more than in 1932 but twelve less than in 1931. Collisions with other vehicles accounted for eighteen of the eighty deaths from this cause. Suicides stood second as a cause of death accounting for fifty-seven deaths. Airplanes responsible for fifty-six deaths were third. Deaths from external causes gave a rate of 2.10, almost as high as the total rate for diseases, 2.11. During the year ninety-two officers and 1,721 enlisted men were discharged from the service on account of physical or mental disability, a total of 1,813 as compared with 1,566 for 1932. The rate of discharge for the year for the entire army was 13.3. The noneffective rate for the whole army for the year was 29.4, as compared with 30.5 for 1932 and 32.5 for 1931. Gonorrhea was the leading cause for the loss of time 2,863 cases accounting for 133,531 days lost. However tuberculosis led the conditions causing the greatest loss of time per case on account of the long continued treatment required. Injuries caused 19.7 per cent of all noneffectiveness, as compared with 18.8 for 1932. The rate 5.6 was the lowest on record for alcoholism for the total army with the exception of the war years. Twelve drug addicts were detected, as compared with sixteen in 1932.

Government Services

Progress in Testing of Cattle

Testing of cattle for tuberculosis is progressing more rapidly than at any time in the history of tuberculosis eradication, according to a statement from A. E. Wight in charge of eradication of tuberculosis and Bang's disease for the U S Department of Agriculture. During November 1934 a total of 212,203 cattle were tested more than in any month in the history of the nation wide campaign. Although the work against Bang's disease is more recent, reports from forty-four states show that more than 286,000 agglutination tests were made in November. Nearly 15 per cent of the cattle reacted and will be removed for slaughter. Large numbers of cattle

The State Assistance of the Unemployed

Following the war the unprecedented unemployment led to equally unprecedented government expenditure for its relief, and controversy arose as to the amount of food necessary for the maintenance of health and its cost. The question was at first scientific but it quickly became political, for, whatever was given, the labor party demanded more. In the house of commons, Mr Oliver Stanley introduced for the government a draft of unemployment assistance regulations. He said that the scales proposed were the result of a careful survey by the Unemployment Assistance Board of the primary needs of the people for whom the board was responsible. There were great differences in the results arrived at by different social surveys. In the spring of 1934 a hotly contested debate took place in the house of commons as to whether the allowance for a child should be 48 or 72 cents a week. (This does not mean that parents were expected to keep children on this expenditure but merely that it is an allowance per child to persons with other resources such as the unemployment dole.) In the new scale the minimum allowance for any child is 72 cents and that amount increases with age, which is a new principle. Dealing with the question of the treatment of resources other than earnings in assessing needs, the basis to be adopted with regard to milk and meals given to children at schools is as follows. All meals given on a physician's certificate that a child is suffering from a specific condition and requires extra nourishment are to be regarded as personal medical requirements and ignored. Milk or other special items, such as cod liver oil, will also be entirely ignored. Meals up to two a day for a single child in a household or one meal for two children will be ignored as constituting a negligible saving for the family. That is to say, twelve meals a week will be free. After that some deduction will be made in respect of those meals, which works out roughly at two cents a meal. As regards medical relief, maternity and child welfare, and tuberculosis services any payments or allowances in kind under these services will be regarded as special needs and will be ignored. In the case of pensions for old age, widows and orphans and the blind, any balance after providing for the pensioner's needs would be allowed for the personal needs when there were no other resources, that is, they would be ignored. In the debate that followed, a physician, Sir Francis Freemantle (a retired health officer), described the new regulations as a great measure but they were opposed by the labor party as inadequate. They were carried by a large majority.

An organization called "The Children's Minimum Committee," formed to ensure the adequate nutrition of children welcomes the new regulations as a considerable advance but points out that for families with two or more children the proposed scale will not permit of an expenditure satisfying the standards laid down by the British Medical Association's Committee on Nutrition. The Children's Minimum Committee urges that the scale should be supplemented by free meals and milk, which should not be taken into account in assessing the family resources.

The Prevention of Mule Spinners' Cancer

The Manchester Committee on Cancer, formed in 1925, is representative of all the hospitals and public health authorities in the city. Its major work has been the establishment of a laboratory unit in the university, primarily for investigating the causes and prevention of mule spinners' cancer so alarmingly

prevalent in the cotton mills of Manchester and the neighboring towns. Increasing incidence of mule spinners' cancer began to be noticed about 1908. This led to the appointment by the government of a special committee of investigation. In 1920 it was reported that the death rate from this form of cancer in cotton operatives was 137 for spinners and 72 for other cotton workers, while the mean national death rate was 4 per million living males. It was found that spinners' cancer was due in part if not entirely, to mineral oil. The Manchester committee therefore undertook an investigation as to the possibility of purifying the mineral oils likely to cause cancer. Their scientists were the first to examine this problem from the special point of view of cotton mills. The results have now reached a practical stage. The amount of work done by pathologists, chemists and physicists in the investigation during the nine years is enormous.

As reported previously (THE JOURNAL, Dec. 22 1934 p 1959), the director of the Cancer Research Laboratories, Dr C. C. Tixort, has been able to lay down a specification for lubricating oils that should reduce the risk of cancer to a minimum. The precancerous conditions of the skin due to handling mineral oils are now being almost altogether prevented by the precautionary measures recommended. These observations constitute the first real preventive work in cancer that has been effected in this country and, so far as is known, in the world. A similar line of investigation is now being carried out in relation to tar compounds and concern gas tar workers, distillers, tarmac road workers, and others. Considerable evidence has been collected to show that the increasing incidence of cancer of the lung is associated with contamination of the atmosphere by smoke. The action of the exhaust fumes of automobiles is also under investigation.

Some mineral oils were found to be more carcinogenic than others, but all other than white oils (such as medicinal liquid petrolatum and the lighter boiling spirits), were potentially carcinogenic. Textile oils were the most carcinogenic considerably more than the heavier internal combustion engine oils. The animal test of carcinogenicity is lengthy, laborious and expensive. To avoid these difficulties the chemical and physical characters of the oils were investigated and the results proved to be of the greatest utility, allowing oils to be condemned or recommended. The refractive index and the specific gravity were the test of greatest value and allowed animal tests to be dispensed with entirely. As a prophylactic against industrial cancers, an ointment composed of equal parts of wool fat and olive oil gave the greatest protection. It is recommended that all parts of the body likely to come in contact with the suspected material should be smeared with this before work is begun. After work the parts should be washed with soap and water and carefully dried, a little of the ointment being again rubbed in.

The Laboratory and the Clinic

In his presidential address to the Royal Society, Sir F. Gowland Hopkins said that practice in the ward and activity in the laboratory, which only a generation ago made few contacts, have now come into close relations, with a degree of mutual respect between their respective workers that was perhaps lacking in the past. It seemed that the minds of some physicians have been disturbed by one aspect of this new orientation. Not doubting that the laboratory has assisted and must continue to assist the growth of medical knowledge, they have felt that the introduction of multitudinous laboratory methods into the domain of diagnosis is tending to destroy the true clinical art. It had been said that the older physicians with minds undisturbed by a crowd of scientific facts developed a clinical sense, sui generis, as subtle as the sense of taste or the sense of smell, and that it was on this sense that the great school of English medicine was founded. The president did

not know whether there was truth in the view that reliance on laboratory reports tended to destroy this sense. Great emphasis was being laid on the fact that, distinct from all the laboratory science which was ancillary to medicine, there was a clinical science, the progress of which depended on the direct and intimate study of disease as manifested by human beings. The need had been expressed for the endowment of a phalanx of trained clinicians who shall bring clinical science to a new pitch of efficiency.

The Relation Between Stammering and Left-Handedness

At the annual Conference of Educational Associations, Dr. Millais Culpin, lecturer on psychoneuroses to the London Hospital Medical School, in introducing a discussion on speech therapy, spoke of the relation between stammering and left-handedness. In right-handed persons, he said the left cerebral hemisphere was trained, but at the same time the right hemisphere was, one might say, acquiring knowledge in mirror fashion. If a man lost his right arm he tried to write with his left hand, and if he was allowed to write in mirror fashion he would do so in a very short time. In a child born left-handed stuttering resulted, according to the view of a famous anatomist, from conflicting control—ineffectual attempt to enunciate by reversal of the proper muscular action. This sounded simple, but there were objections to the theory. The same anatomists said that to a sensitive child the mental conflict that might arise from such causes might have serious consequences on the temper and character. What kind of person, however, was the left-handed? The left-handed had a peculiar make up. They were calm and deliberate, they demanded justice for themselves and others, and they showed a spirit of deliberate obstinacy. They did not get wild, they just calmly went on their own road. In the discussion which followed Dr. E. J. Boone, director of speech therapy of the London County Council Schools, said that speech therapy was coming into its own and had come to stay. His own experience was that stammering was definitely curable.

Foreign Physicians in France

According to de Lafond, the number of foreigners practicing medicine in France was 99 per cent of the total of 26,205 physicians in 1931. In the latter year, 28.2 per cent of the licenses in Paris were given to foreigners. There were only 429 medical students of foreign birth in 1920 and 1,511 in 1930 out of a total of 4,500 in the Paris medical school.

There are a number of ways to explain this plethora of foreigners. One is the reputation of the Paris school. Another is that the number of medical students has been greatly restricted by legislation in Brazil, the United States, Canada, Sweden and a number of other countries. A third reason is that many prizes and cheap living quarters in the Cite universitaire tempt the foreign student to come to France. Last of all, especially since the World War, France has become a harbor of safety for the refugees from all other countries such as Russia and more recently Germany.

There will be a decided reduction in the number of medical students and hence of practitioners of foreign birth in the near future. A new law termed the Armbruster law abolishes permitting foreigners to be excused from any of the required work in the medical school. Heretofore they could be admitted to the fourth year and thus were obliged to pass the examinations only of this and the final or fifth year. In the future, the full six years in the medical school and a bachelor of arts degree from a French university will be required of every foreigner the same as for any native student. Up to the present,

Rumanian students have not been obliged to pass the French baccalaureate examinations. In 1933 more than 700, or about one sixth of the students, in the Paris medical school were Rumanian who had taken advantage of such a clause in a treaty between France and Rumania dating back to 1860.

No one will be permitted to practice medicine in France unless he becomes naturalized. The only exception is that in the case of countries like the United States and England, which allow a French citizen to obtain a license without becoming naturalized, are exempt from this portion of the Armbruster law, which is now in effect. Of course, in about one third of the states in the case of the United States, an applicant for a license must agree to become a citizen. As a result of the Armbruster law, the number of American and English physicians in France will be greatly lessened and possibly may reach a negligible figure.

In the past, the medical schools have granted a diploma, termed "Diplome universitaire," which did not carry with it the privilege to practice in France or its colonies. If as many foreigners continue to take the courses as in the past, there will be but little relief from the present overcrowding in the medical schools, even though the Armbruster law is in effect. Fortunately, the economic crisis existing in the majority of countries has begun to decrease the number of foreign students in France since 1931, at which period there were 17,281, while in 1934 there were only 14,495. That medical schools are stricter in granting diplomas is shown by the fact that in 1931, 1,446 were given in a total of 7,336 medical students, while in 1933 there were 12,407 students in the medical schools but only 1,552 diplomas were bestowed.

Is Phrenic Resection Beneficial in Pulmonary Tuberculosis

In the Dec. 1, 1934, issue of the French medical gazette, the results of seventy-four phrenicectomies are reported by Delay, Colbert and Mollard. The three indications for the operation were, first, those cases of pulmonary tuberculosis in which a pneumothorax had not been followed by any improvement or was impossible because of pleural bands or adhesions. The second group included cases in which the resection of the phrenic nerve supplemented the pneumothorax. Later, and this forms the third group, the nerve resection was done primarily in preference to a pneumothorax, either because the latter appeared contraindicated by extensive bilateral lesions or because the lesions in the lung were still too recent.

No complications were observed in the seventy-four cases in which phrenicectomy was performed such as gastric disturbances or lighting up of foci on the same or opposite side. In one third of the cases there was considerable pain during the operation due to prolonged search for the nerve. There are also some cases in which one finds anomalies, such as that the nerve that was resected is found, after the operation not to have contained any of the motor fibers for the diaphragm.

As to the results of the seventy-four operations, thirty-one patients were markedly and eleven only slightly (symptomatically) improved. Thirty-two cases failed to show any benefit from the nerve resection. In the thirty-one in which there was marked improvement the lesions in the immobilized lung had diminished in size and the clinical symptoms had disappeared completely. None of these thirty-one cases had shown previously any improvement after prolonged sanatorium treatment. Eight of the thirty-one can be considered as completely recovered. The less active the lesions the greater is the chance of success after phrenicectomy. If the lesions occupy half or two thirds of a lung the operation is of no avail. Phrenicectomy is especially useful for lesions of the base hilus or central regions of the lung. The nerve should be resected for a distance of 7 or 8 cm.

Research on Leukemia

Since the essential nature of leukemia has appeared to be less in the increase in the leukocytes than in the tumor-like proliferations of the blood-forming organs leukemia has been classified with the malignant tumors by some investigators. Leukemia has been considered a true tumor of the hematopoietic tissue, usually accompanied by a flooding of the blood stream with a large number of immature cells. Objections have been made to the interpretation of leukemia as a tumorous condition but no agreement has been reached. Dr. Walter Büngeler of the pathologic institute in Danzig has attempted to produce experimentally in mammals, leukemia, aleukemic myelosis, lymphadenosis and lymphosarcoma. Büngeler was able to demonstrate that the development of leukemia takes place according to the same laws as do malignant tumors, and, moreover, that the tissue metabolism of leukemic proliferations differs in no respect from the tissue metabolism of malignant growths.

Disturbances in embryonal development are the first factors in the etiology of leukemia, and this is the case also in malignant growths. Congenital leukemias have been described repeatedly. Then there are studies based on the regeneration theory. Fischer-Wasels in Frankfurt-on-Main as well as Büngeler demonstrated that regenerative processes which under normal conditions lead without exception to complete restoration frequently become the seat of a tumor formation, if in the experimental animals a predisposition has been produced by the prolonged administration of tar or arsenic. This predisposition can be recognized by certain changes of the metabolism. The parenteral administration of indole produces similar metabolic changes as those resulting from the administration of tar and arsenic. In studies on indole Büngeler observed peculiar organic changes on the hematopoietic tissue. A large number of the white mice die within the first eight weeks with the signs of poisoning if they are subjected to intensive indole treatment, in others hemolytic anemias developed accompanied by a reduction in the leukocytes and by hemorrhages and necroses in the bone marrow, in the spleen or in the liver. During the eighth month of the indole treatment, tumor-like proliferations of the hematopoietic organs develop in a large percentage of the animals. Apparently it depends on constitutional factors whether under the influence of the same treatment, one group of animals develops a tumor of the lymphatic tissues or a tumor of the myeloid tissue. However, the observation that the same experiments may result in leukemia or in lymphosarcoma justifies the conclusion that the two conditions are closely related. These experiments prove that leukemias, like other malignant tumors may develop on the basis of regenerative processes. Accordingly the pathogenesis of this fatal disease is governed by the same laws as is that of other malignant tumors. Moreover, the leukemic proliferations have a metabolism which, with its greatly increased fermentation, resembles in all respects that of malignant growths. Büngeler concludes that leukemia is a malignant growth of the blood-forming apparatus. Lignac recently arrived at the same results by means of chronic poisoning with benzene. Indole is a compound that develops in the course of intestinal putrefaction. These studies are carried on with the support of the Lady-Tata Memorial Foundation.

Silicic Acid in Blood of Patients with Silicosis

In the Kaiser Wilhelm Institute in Dortmund and Münster (Westphalia) experiments on silicosis have been conducted for some time. They were discussed in *THE JOURNAL*, Feb. 10, 1934, page 471. Prof. Heinrich Kraut determined previously that the silicic acid content of the blood of normal persons

amounts to from 1 to 3 per cent of the ash. The average value of the silicic anhydride in the blood ash of sixty persons was 1.8 per cent. The limits were 1.5 and 2.1 per cent, respectively. Tests on seventy-nine patients with silicosis revealed that their blood ash nearly always had high silicic acid values, on the average 3.5 per cent of silicic anhydride. The values fluctuated between 2.4 and 4.5 per cent. Patients with silicosis thus have an increased silicic acid content of the blood, that is, dissolved silicic anhydride has been absorbed by the organism. To determine the length of time a miner works on rock formations containing silicic acid before these chemical influences on the organism become manifest, the blood of 265 miners was tested for the silicic acid content in connection with the roentgenologic examination to which they were subjected at regular intervals. The blood ash of these workers has about the same average silicic anhydride content as has that of other persons, namely, 1.9 per cent, but the upper and the lower limits are considerably farther apart (3.1 and 1 per cent). In workers without demonstrable silicotic changes the upper and lower limits of the silicic acid content move farther apart within the first six years of time they have worked on silica rock, and in the following twelve years the movement is primarily upward. In workers who develop a slight silicosis within the first six years without becoming incapacitated a great increase becomes noticeable up to 3.8 per cent of silicic anhydride. In the two subsequent six-year periods, this increase partly subsides again, doubtless because men with high silicic acid content of the blood are eliminated from the group, because of severe silicosis. This is indicated not only by the comparison with the values of those silicosis patients no longer able to work but also by the results of the examinations of miners who have worked on silica rock more than eighteen years in whom the values closely approach once more the upper and lower limits in normal persons. This is the case particularly in workers without signs of silicosis and also in those who already have a slight silicosis. The wide fluctuations prevent as yet the elimination of those who are in danger on the basis of the abnormal silicic acid values of their blood.

The Psychiatric Examination of van der Lubbe

Professor Bonhoefer, director of the psychiatric clinic of the University of Berlin, and his assistant Dr. Zutt have published the testimony they rendered in the case of M. van der Lubbe, the incendiary of the Reichstag fire. They stress that, on the basis of the public trial, it was impossible to get a clear picture of van der Lubbe's mental condition, and this fact has favored the spread of phantastic rumors. For persons with psychiatric training it would have been unnecessary to refute the explanation that the behavior of the defendant was due to hypnosis and the administration of scopolamine; nevertheless, they examine these charges briefly and call attention to the absence of dilatation of the pupils and of all signs of a narcotic or hypnotic condition. The scientific value of the neuropsychiatric examination would have been greater in case of a conclusive solution of the case which was not accomplished. But even with this limitation the psychiatric testimony is of interest. While the authors deny the existence of a disturbance of the consciousness when the deed was committed this does not prove that van der Lubbe was normal. They consider him a psychopath who has to be considered accountable for his actions. His mutistic behavior during the trial is interpreted as a spite reaction. It was not an intentionally assumed attitude but rather a psychogenic-reactive state that can be compared to the obstinacy stupors of children. The outburst on the forty-second day of the trial on which van der Lubbe talked for the first time of inner voices was no surprise to the psychiatrists. It is interpreted as the expression of a prison reaction. However, the attitude of the defendant during the entire duration of the imprisonment the affective inexorability and the consequent

moroseness, is an astounding performance, which is understandable when it is considered that van der Lubbe was an extraordinary person. According to the psychiatrists, he was a confused fanatic with a mixture of craving for applause and self sacrifice, good natured responsiveness and an attitude of defiance. His average intelligence was not equal to his essentially mental interests, but in spite of this he showed an astounding determination by steadfastly refusing to identify the accomplices he may have had. The expert in matters of arson questioned the statements of van der Lubbe, and that may have been a contributory cause in the outburst on the forty-second day of the trial. The two psychiatrists reach the conclusion that the psychopathically predisposed defendant cannot be considered mentally diseased.

VIENNA

(From Our Regular Correspondent)

Dec 10, 1934

The Birth and Death Rates

The federal ministry for public health recently published a summary of the status of the population of Austria of the last few years. The decrease in the birth rate has advanced further. Compared with the preceding year the numbers were as follows:

	1932	1933
Total number of births	105 514	98 861
Total number of deaths	93 721	89 071
Excess of births	11 793	9 790

Thus the excess of births was reduced by 2 000. If one looks back twenty years the falling birth rate is even more evident. There were born in the region of present-day Austria and in Vienna

	In Region of Present Day Austria	In Vienna
1913	169 060	39 155
1923	155 704	29 691
1933	98 861	13 746

That reveals for Austria a reduction in births of more than 70 000, or 40 per cent and for Vienna alone more than 66 per cent (26 000) in twenty years. Whereas in Vienna the status of the population is kept at the same level only by immigration from the provinces—the death rate far exceeds the birth rate—there is still a slight excess of births in the provinces but this will probably disappear within the next ten years if there is no noticeable change in the mortality. Ten years ago (1923) the number of deaths in Austria per thousand inhabitants was 15.3, the births 22.5 that is, there was an excess of births amounting to 7.2. In 1933, however the death rate was 13.6 the births only 15.1, an excess of 1.5, which doubtless will soon disappear. For Vienna the figures are

	1923	1933
born per thousand inhabitants	15.9	7.3
deaths per thousand inhabitants	13.7	13.6

that is, an excess of deaths over births of more than 6 per thousand inhabitants. The mortality is constantly decreasing. There is a shifting of the average age at death into the higher age groups. The population becomes older as shown in the following tabulation of 1,000 deaths, as to the age group

	1923	1932	1933
0 to 5 years	246	149	128
5 to 15 years	29	26	26
15 to 30 years	80	63	60
30 to 50 years	132	137	131
50 to 70 years	266	310	317
Over 70 years	246	324	338

The death rate of nurslings is likewise constantly decreasing. Of 1,000 live births there died during the first year of life

	1923	1932	1933
In Vienna	110	75	64
In Austria	140	106	94

The mortality rate of nurslings is satisfactory since it is constantly decreasing. However the growing reduction in the birth rate as demonstrated above is to be deplored. There is

still a constant number (above 4 per cent) of births that take place without trained helpers. This is explained by the considerable number of women who live in forests and in the mountains. The number of stillbirths likewise is about constant, on the average 2.5 per cent during the last ten years. The number of illegitimate births likewise remains about the same, about 2.6 per cent.

As regards the causes of death, the diseases of the heart and of the circulatory system take the first place, 15,966, then follow malignant tumors 11,249, then tuberculosis in all its forms, 8,086, then pneumonia, 7,383, then apoplexy, 5,838. Infectious diseases (with the exception of children's diseases) caused 1,590 deaths, wound infections, 1,370, fatal injuries due to accidents caused 2,287 deaths, the number of suicides was 2,853 and the homicides 198. Only 244 women died of puerperal sepsis. This number is rather small when it is considered that over 4,000 births take place without assistance. During the last five years there was not a single fatality due to smallpox, typhus and cholera, but diphtheria caused 990 fatalities, whooping cough 147, scarlet fever 124 and measles 89 (compared to 300 in the previous year). On the whole, the children's diseases caused a much greater number of fatalities during the previous year. Cholera infantum caused 526 (compared to 813). Abdominal typhoid caused 121 fatalities and dysentery 21. The reports of recent years show with increasing clarity that the mortality rate of cardiac and cerebral disorders steadily increases, relatively as well as absolutely. These two factors are now responsible for 20 per cent of all deaths, while twenty years ago they were responsible for only 12 per cent.

Investigation of Methods of Irradiation of Carcinomas

At a recent session of the Vienna Society for Roentgenology, Dr. A. Frank reported about his studies on the method of irradiation of large carcinomas consisting of pavement epithelium. Half of the carcinoma was irradiated with one large dose (1,800 roentgens), while the other half was daily irradiated with a so-called fractional dose consisting of 200 roentgens until a total of 4,000 roentgens had been reached. The quality of the rays and the roentgen minute dose were the same. By the time 1,000 roentgens had been administered to the side that was given the fractional irradiations a considerable decrease in the size of the tumor was noticeable, while the side to which the single large dose had been applied showed no macroscopic signs of a change, in spite of the fact that the surrounding skin, which had been exposed to this radiation reacted noticeably. When 1,800 roentgens had been reached, the same dose that the other side had had, the tumor had largely disappeared on the side irradiated with the small doses, while on the other side macroscopic changes were still lacking. In the further course it was observed that on the side to which the single, large dose had been applied the tumor was still partly in evidence, while it had completely disappeared on the side to which the fractional doses had been applied. Histologic studies revealed that on the side of the fractional irradiations the tumor cells were destroyed by undergoing cornification and maturation, while on the side of the large dose a vacuolizing degeneration took place. Studies conducted in several other suitable cases led to the same results. In view of these observations, Dr. Frank formulated the thesis that the application of a single large dose leads to a less rapid disappearance of a tumor than the fractional irradiations. This factor is important when the danger of metastasis is considered, for it has been assumed erroneously that in case of fractional irradiation the danger of metastasis is greater. In the discussion it was pointed out that the nature of the cells of the neoplasm as well as its reaction capacity to the x-rays is of great importance in the evaluation of a method of irradiation. However, many agreed that fractional irradiations are generally to be preferred.

Pictures of a Giant

Prof D H Fuchs, who recently returned to Vienna from the Orient, showed at the last meeting of the Society of Physicians photographs of a giant, whom he had seen in Bushire, Persia. The giant was 10 feet 6 inches (3.2 meters) tall and was 19 years old. He had developed normally up to his tenth year, when he began to grow enormously. Mighty humps developed on his forehead, chin and behind the ears. The head became so heavy that the man could not hold it up. The humps on the forehead caused a great forward curvature. They have the appearance of tumors. There are many other lighter, loose nodules in the wrinkled skin. In the enormous head the eyes appear, in spite of their normal size, extremely small; the vision is good and the teeth are normal. The extremities are of an enormous length, the proximal phalanx being as long as the index finger of a normal man. The legs are too weak to enable him to walk, so he is generally lying down, but he is able to stand up when supported by a cane. His intelligence is almost normal, he complains frequently of vague pains. Recklinghausen's disease has been considered as the etiologic factor and it is assumed that an early localization of the process in the hypophysis or in the growth center is responsible for the giant growth. The patient was unable to ride in an ordinary carriage and he had to be placed on a boat by means of a crane. His weight exceeded 200 Kg (450 pounds).

ROME

(From Our Regular Correspondent)

Dec 31, 1934

The Readjustment of Clinically Cured Tuberculous Patients

Dr Alfonso Muzzarelli of the Consorzio Provinciale Antitubercolare of Florence reported the results of studies on readjustment to work of tuberculous patients who have been discharged from sanatoriums as "clinically cured." When these patients reenter work, they are confronted by demands beyond their physical conditions. It seems advisable therefore to establish postsanatorial colonies adjacent to the sanatoriums to prepare patients for work while still under medical supervision. A temporary regimen for tuberculous patients in these colonies will result in the correction of lazy habits acquired during their long stay in the sanatoriums. It will also open up new fields of work when the work previously done has to be changed more in accordance with the type of cure obtained in the given case.

Prizes in Ophthalmology

The Società Italiana di oculistica has reviewed the most important articles presented in the annual competition for ophthalmologic prizes. The awards were as follows: The national prize, 20,000 lire (about \$1,400), to Dr Parnico of Rome for an article on biomicroscopy of the palpebral margins, and of conjunctivitis. The first international prize, 20,000 lire to Dr Benedetto Strampelli for an article on biomicroscopy and histology of cataract with polarized light. The second international prize to Dr Nordmann of Strasbourg for his physico-chemical studies of the crystalline lens in normal and pathologic conditions.

The National Congress of Pediatrics

The fifteenth National Congress of Pediatrics was held at Sienna, with a large attendance from Italy and abroad. The first topic was "Sepsis in New-Born Infants and Nurslings." Dr Bocchini said that sepsis causes symptoms of a grave general infection that overshadow those of the first focus of infection. The predisposition to the development of sepsis in infants is related to their conditions of immunity. A passive but transient immunity is acquired from the mother, which protects them against diseases to which the mother herself is immune. This defense mechanism in infants is built up by

organic processes of slow evolution and may be weak against pyogenic infections because of minimal cellular reactions and the scant activity of the phagocytes. Breast feeding provides the child with the proper nutrition whereby the organism can promptly meet the immunologic demands. Artificial feeding may cause nutritional disturbances that result in a lowering of the defense against infections. A diminished amount of vitamins in the milk, environmental conditions, and the existence of some constitutional diathesis are the most important factors in the onset of septic infections.

Dr Gerbasì discussed the pathology, blood picture, diagnosis, prognosis, prevention and treatment of sepsis. The most important changes are in the liver, respiratory tract, adrenals and bones of the skull. The blood picture is not definite and it has a prognostic value only when it is within certain limits. Immature erythrocytes and leukocytes frequently appear in the blood, simulating the picture of anemia of the Jaksch-Hayem type. The roentgen examination of skeletal foci gives diagnostic results as satisfactory as those given by the bacteriologic examination of the blood. Prevention depends largely on the care of infants and their environment. The attempts at immunization in the prevention and therapy of sepsis have not given satisfactory results as yet.

Dr Vaglio said that attenuated forms of sepsis are difficult to diagnose and may be mistaken for nutritional disturbances, prematurity and congenital weakness. Sepsis may be of the hyperacute, acute or attenuated form. Symptoms similar to those observed in sepsis may be observed also in diphtheria, alimentary toxicosis, malaria, tuberculosis and congenital syphilis. The members of the congress voted to recommend a revision of the projects concerned with the construction of pediatric institutions, special training for the personnel concerned with the care of infants, and the provision of sterilized linen for them.

The second topic was "Indications for Climatotherapy for Infants." Dr Bentivoglio classified climates into stimulative, sedative and indifferent, and insisted on the importance of establishing a classification for each climatic station.

Dr Magni spoke on the indications for the sojourn of children at the seashore. He concluded that the climate at the seashore is a powerful agent for the prevention and treatment of certain infantile diseases, especially certain forms of external tuberculosis, rickets and peribronchial adenopathies.

The third topic was "The Sympathetic Nervous System in Infants." Dr Careddu said that this subject should be considered, as yet, a program to be developed rather than as an exposition of results already acquired. He discussed the evolution of the sympathetic cells, which need several years during the first two decades of life to reach their complete development and definite adjustment. The main function of the sympathetic nervous system is the regulation of the internal equilibrium of the body by means of rhythmic sympathetic, visceral, motor and sensory reflexes. The parasympathetic energies predominate during childhood in order to provide a greater activity to the anabolic processes.

Dr Guassardo said that the physiology and pathology of infants are chiefly controlled by the vagus nerve, the preponderance of which determines an exaggerated reaction of the body to even slight stimulations, which may result in disturbing the normal sympathetic equilibrium necessary for the conservation of health. The development of diseases in infants depends on the constitutional tendency, and that statement applies especially to such diseases as exudative diathesis, spasmophilia, anaphylaxis and cyclic vomiting. That is why the conception of the existence of a hypervagal sympathetic diathesis establishes a bridge connecting the pathology of the parents with the future morbid predisposition of the children.

The next national pediatric congress will meet at Genoa.

Marriages

CHARLES LEE ANDERSON to Miss Frances Elizabeth Behnes, both of Jackson Heights, N Y, Dec 21, 1934

WILLIAM JOHN MACKENZIE to Miss Enid Howell, both of Vancouver, B C, Canada, Dec 15, 1934

JACOB MOSCOVICH to Miss Mary Armstrong, both of Vancouver, B C, Canada, Nov 30, 1934

MOSES KAHN ROSENBAUM, Milwaukee, to Miss Pearl Finnegan, in Chicago, Dec 22, 1934

SAMUEL E. KOHN, Milwaukee, to Miss Rita Jane Goldman of Whitefish Bay, January 10

THOMAS HARDGROVE to Miss Evelyn O Leary, both of Milwaukee, Dec. 29, 1934

LAWRENCE M CALDWELL, Newton, N C, to Miss Macel Ratchford, January 4

BENJAMIN POLOW to Miss Buddy Wachstein, both of Newark, N J, January 23

MONTÉ SALVIN to Miss Joyce Tichnor, both of Los Angeles, January 26

Deaths

Clarence Pierson ☉ Pineville, La, Tulane University of Louisiana Medical Department, New Orleans, 1894, member of the House of Delegates of the American Medical Association, 1919-1920, past president, and formerly councilor of the sixth district, Louisiana State Medical Society, member of the American Psychiatric Association, past president of the Louisiana Hospital Association, veteran of the Spanish-American War, parish coroner, 1896-1900, at one time bank president, formerly medical superintendent of the Central Louisiana State Hospital, Pineville, and the East Louisiana State Hospital, Jackson, special consultant to the three eleemosynary institutions for the insane and feebleminded, Central Louisiana State Hospital, Pineville, East Louisiana State Hospital Jackson, and the State Colony and Training School, Alexandria, aged 66, died, Dec. 27, 1934, in the Touro Infirmary, New Orleans, of carcinoma of the stomach

Alfred Owre, Pine Plains, N Y, Minneapolis College of Physicians and Surgeons, 1895, also a dentist, dean and professor of dentistry, School of Dental and Oral Surgery, Columbia University, 1927-1934 student assistant in operative dentistry, 1893-1894, instructor in dental metallurgy, 1895-1896, instructor in operative dentistry and dental metallurgy, 1896-1897, clinical professor of operative dentistry in 1899 and dean and professor of theory and practice, 1905-1927, College of Dentistry, University of Minnesota member of various international dental congresses, past president of the Minnesota Dental Association, special consultant in dentistry, Presbyterian Hospital New York, aged 64 died, January 2, in the Beth Israel Hospital, New York

Gaston Holcombe Edwards ☉ Orlando, Fla, Yale University School of Medicine, New Haven, 1902, member of the House of Delegates of the American Medical Association in 1925 and in 1931, fellow of the American College of Surgeons, councilor of the seventeenth district and past president of the Florida Medical Association, Florida Railway Surgeons' Association and the Orange County Medical Society, aged 59, consulting gynecologist and obstetrician to the Florida Sanitarium and Hospital and chief of staff department of gynecology and obstetrics at the Orange General Hospital where he died, Dec. 29, 1934, of heart disease

Leonard Samuel Hughes ☉ Lieut Colonel, U S Army, retired, Los Angeles, Louisville (Ky) Medical College, 1897, a contract surgeon from 1898 to 1908 when he was commissioned in the medical reserve corps as a first lieutenant and served in this capacity until 1911 when he was appointed first lieutenant in the medical corps, promoted to major in 1917 in 1918 was commissioned lieutenant colonel in the National army and reverted to his permanent rank of major in 1920 retired in 1922 and promoted to lieutenant colonel retired in 1930, aged 62, died, January 3, of ruptured duodenal ulcer and peritonitis.

Henry Maynadier Fitzhugh ☉ Westminster, Md, University of Maryland School of Medicine, Baltimore, 1897 member of the House of Delegates of the American Medical Association 1933-1934, president of the Federation of State Medical Boards of the United States since 1910 member and

since 1924 secretary and treasurer of the state board of medical examiners in 1930 president of the Medical and Chirurgical Faculty of Maryland, president of the state board of education, aged 59 died, January 25 in the University Hospital, Baltimore, of acute streptococcal osteomyelitis of the femur

Edmund Brown Piper ☉ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1911, professor of obstetrics at his alma mater and the graduate school of medicine member of the American Gynecological Society, fellow of the American College of Surgeons, served during the World War, obstetrician to the Pennsylvania Hospital and Hospital of the University of Pennsylvania, gynecologist to the Philadelphia General Hospital, consulting obstetrician to the Bryn Mawr (Pa) Hospital, aged 53, died, January 14, of angina pectoris

Thomas Morris Murray, Pomfret Center, Conn, University of Maryland School of Medicine, Baltimore, 1873, at one time emeritus professor of physical diagnosis, laryngology and rhinology, Georgetown University School of Medicine, Washington, D C., formerly on the staffs of the Emergency and Garfield hospitals, Washington, aged 83, died, Dec 16 1934, of coronary thrombosis, diabetes mellitus and cirrhosis of the liver

Alfred Goldstein Nadler, New Haven Conn Yale University School of Medicine, New Haven, 1896, member of the Connecticut State Medical Society, clinical professor of dermatology at his alma mater, member of the New England Dermatological Society and the American Roentgen Ray Society, on the staffs of the New Haven Hospital and St Raphael's Hospital, aged 61, died, January 14, of heart disease.

Albert James Welch ☉ Kansas City, Mo, Starling Medical College, Columbus, 1894, past president of the Jackson County Medical Society, councilor to the thirteenth district of the Missouri State Medical Association, served during the World War in the public health department stationed at Washington, D C., aged 67, on the staff of St Joseph's Hospital, where he died, Dec 15, 1934, of coronary heart disease

Oscar L Norsworthy, San Antonio, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1895, member of the State Medical Association of Texas fellow of the American College of Surgeons, formerly member of the board of health of Houston, director of radium and cancer division, Medical and Surgical Hospital, aged 63, died, January 5, in Los Angeles, of heart disease.

Bertram H Buxton, Byfleet, Surrey, England New York University Medical College, 1897, in 1898 instructor in bacteriology, in 1903 associate professor of biology and in 1904 to 1912 professor of experimental pathology, Cornell University Medical College, New York, formerly on the staff of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, aged 80, died, Dec. 6, 1934

Richard Penn Smith ☉ Captain, U S Army, retired, Philadelphia, Temple University School of Medicine, Philadelphia, 1912 veteran of the Spanish-American and World wars, entered the medical corps of the U S Army in 1920 and retired in 1928 for disability in line of duty, aged 59 on the staffs of the Germantown Hospital and the Temple University Hospital, where he died, Dec. 23, 1934, of hypertension and nephritis

William Fitzhugh Carter ☉ Major, U S Army, retired, Crozet, Va University of Virginia Department of Medicine, Charlottesville, 1872, entered the army as assistant surgeon in 1879 and was promoted through the various grades to that of major in 1897, retired in 1909 at his own request after thirty years' service, aged 84, died, January 1, in Richmond, of lobar pneumonia

John Rowan Morrison ☉ Louisville, Ky Louisville Medical College, 1898 formerly adjunct professor of medicine and clinical medicine, University of Louisville School of Medicine fellow of the American College of Physicians, on the staffs of the Norton Memorial Infirmary and St. Joseph's Infirmary, aged 57, died, January 8 of arteriosclerosis

George Morley Marshall ☉ Philadelphia, University of Pennsylvania School of Medicine Philadelphia, 1886 formerly associate professor of laryngology, University of Pennsylvania Graduate School of Medicine, fellow of the American College of Surgeons, otolaryngologist to St Joseph's Hospital, aged 76, died, January 8, of heart disease

Howard Donald Urquhart ☉ New York, University and Bellevue Hospital Medical College, New York 1906, formerly clinical professor of orthopedic surgery New York Polyclinic Medical School and Hospital formerly on the staff of the Seaside Hospital, Staten Island, aged 55, died, Nov 8 1934, of heart disease

Jacob William Holderman, Duluth, Minn., Rush Medical College, Chicago, 1918 member of the Minnesota State Medical Association, formerly resident in laryngology and otology at his alma mater, on the staffs of St. Mary's and St. Luke's hospitals, aged 44, died suddenly, January 22, of coronary thrombosis.

Warren Wallace St. John & Trov, N. Y., Columbia University College of Physicians and Surgeons, New York 1905, past president of the Rensselaer County Medical Society, president of the hospital staff of the Samaritan Hospital, aged 52, died, Dec. 22, 1934, of cerebral thrombosis and cerebral arteriosclerosis.

Charles Egbert Willard, Catskill, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, 1869, member of the Medical Society of the State of New York, for many years treasurer of Green County, and village health officer, aged 88, died, January 12, of arteriosclerosis.

John Harvey Graff, Perryville, Mo., Chicago College of Medicine and Surgery, 1916, served during the World War for many years connected with the U. S. Public Health Service, aged 41, died January 6 in the Veterans' Administration Facility, Jefferson Barracks, following a thyroidectomy.

Beverley Z. Milner, Toronto, Ont., Canada, Trinity Medical College, Toronto, 1889, for many years on the staffs of the Toronto General Hospital and the Hospital for Sick Children, aged 69, was found dead slumped over the steering wheel of his automobile, Dec. 7, 1934, of heart disease.

Oscar Simon Hornick, Brooklyn University and Bellevue Hospital Medical College, New York, 1928 member of the Medical Society of the State of New York, aged 34, on the staff of the Israel Zion Hospital where he died, January 7, of osteomyelitis of the jaw and cerebral abscess.

Edward Smith Winslow, Harwich Port, Mass., Dartmouth Medical School, Hanover, N. H., 1892 member of the Massachusetts Medical Society, served during the World War, on the staff of the Cape Cod Hospital Hyannis, aged 68, died Dec. 28, 1934, of cerebral hemorrhage.

James M. Shields & Seymour, Ind., Kentucky School of Medicine, Louisville, 1881, president of the Jackson County Medical Society, formerly mayor of Seymour, formerly on the staff of the Schneck Memorial Hospital, aged 75, died suddenly, Nov. 30, 1934, in New York.

John Howard Wyman, Medway, Mass., Harvard University Medical School, Boston, 1906, served during the World War, medical examiner of Norfolk County, aged 55, on the staff of the Milford (Mass.) Hospital, where he died, Dec. 17, 1934, of cerebral hemorrhage.

Homer Monroe Mace, Peekskill, N. Y., University of the City of New York Medical Department, 1890 member of the Medical Society of the State of New York, aged 70, on the staff of the Peekskill Hospital where he died, January 6, of splenic infarct and leukemia.

Wilton McCarthy, Des Moines, Iowa, Drake University Medical Department, Des Moines, 1894 member of the Western Surgical Association, fellow of the American College of Surgeons, formerly professor of clinical surgery at his alma mater, aged 62, died Dec. 14, 1934.

Charles Lincoln Mohr, Jersey Shore, Pa., College of Physicians and Surgeons, Baltimore, 1885, member of the Medical Society of the State of Pennsylvania, for many years on the staff of the Jersey Shore Hospital, aged 70, died Dec. 19, 1934, of heart disease.

Benjamin Franklin McMillan, Red Springs, N. C., University of Maryland School of Medicine, Baltimore, 1882, member of the Medical Society of the State of North Carolina, formerly member of the state legislature, aged 81, died, January 14, of pneumonia.

Peter Alfred Kearney, San Francisco, Cooper Medical College, San Francisco, 1884, at one time superintendent of the San Francisco County Hospital, aged 87, died, Dec. 15, 1934, in the Alameda (Calif.) Sanatorium on the South Shore of coronary thrombosis.

Alvin Barney Eberhart, McDonough, Ga., Emory University School of Medicine, Atlanta, 1922 member of the Medical Association of Georgia, served during the World War, aged 44, died, Dec. 28, 1934, of gastric hemorrhage resulting from carcinoma.

Frank Eli Hurrell, Little Rock, Ark., University of Arkansas School of Medicine, Little Rock, 1911, also a pharmacist, member of the Arkansas Medical Society, aged 53, died, January 14, in a local hospital of injuries received in an automobile accident.

Henry Jeter Edmonds, Kilmarnock, Va., University of Maryland School of Medicine, Baltimore, 1887, member of the Medical Society of Virginia, past president of the Northern Neck Medical Society, aged 68, died, Dec. 13, 1934, of cerebral hemorrhage.

Thomas Melchor Meisenheimer, Charlotte, N. C., Medical College of the State of South Carolina, Charleston, 1925 member of the Medical Society of the State of North Carolina, aged 37, died, January 4, in the New Charlotte Sanatorium, of leukemia.

Leonidas A. Suggs, Park Place, Ore., Vanderbilt University School of Medicine, Nashville, Tenn., 1892, member of the State Medical Association of Texas, past president of the Tarrant (Texas) County Medical Society, aged 70, died, Dec. 7, 1934.

Robert Andrew Poynton, Chicago, Niagara University Medical Department, Buffalo, 1891, on the associate staff of the South Chicago Hospital, aged 69, died, January 22, of uremia, cerebral arteriosclerosis and subacute coronary thrombosis.

W. Francis B. Wakefield, Los Gatos, Calif., Trinity Medical College, Toronto, Ont., Canada, 1893, University of Toronto Faculty of Medicine, Toronto, 1893, fellow of the American College of Surgeons, aged 68, died Dec. 4, 1934.

Joseph Albertus Hedding, Minneapolis, Minneapolis College of Physicians and Surgeons, 1906, member of the Minnesota State Medical Association on the staff of St. Barnabas Hospital, aged 51, died, Dec. 26, 1934, of hypertension.

Jesse Gullledge, Tallahassee, Ala., University of Alabama Medical Department, Mobile, 1900, member of the Medical Association of the State of Alabama, aged 61, died Dec. 19, 1934, in the Community Hospital, East Tallahassee.

James I. Miller, Huntington, W. Va., College of Physicians and Surgeons, Baltimore, 1906, aged 55, died, January 6, in a local hospital of pneumonia, as the result of burns received in a gas explosion in the basement of his home.

John Aulde, Philadelphia, Jefferson Medical College of Philadelphia, 1882, formerly demonstrator of physical diagnosis and clinical medicine, Medico-Chirurgical College of Philadelphia, aged 88, died Dec. 23, 1934.

Clarence C. Spicher & Johnstown, Pa., Baltimore Medical College, 1903, aged 62, chief on the medical service of the Conemaugh Valley Memorial Hospital, 1921-1934, where he died, January 1, of heart disease.

Lewis Joseph Hammers, Goodland, Kan., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, aged 57, died January 19, of angina pectoris and coronary thrombosis.

Josiah Winslow Edgerly, New York, University and Bellevue Hospital Medical College, 1899, member of the Medical Society of the State of New York, aged 62, died, January 14, of lymphatic leukemia.

George Alexander Angus, Denver, Denver Homeopathic College, 1906, aged 64, died, Dec. 11, 1934, in the Denver General Hospital, of ataxic paraplegia, chronic pernicious anemia and myocarditis.

Rankin Robert Lowery, Augusta, Ga., Atlanta Medical College, 1916, served during the World War, aged 43, died, Dec. 23, 1934, in Veterans' Administration Facility, of epidemic (lethargic) encephalitis.

Frederick Huhne, Kingston, N. Y., University of Vermont College of Medicine, Burlington, 1884, for many years member of the board of health of Kingston, aged 78, died, January 4, of chronic arteriosclerosis.

Charles Webb Sheppard, Honoraville, Ala., Southern Medical College, Atlanta, 1891, member of the Medical Association of the State of Alabama, aged 73, died, Dec. 9, 1934, of acute nephritis.

Daniel A. Wilson Sr., Norristown, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1890, served during the World War, aged 67, died, Dec. 22, 1934, of cerebral hemorrhage.

Reginald James Peer, Bangor, Maine, University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1930, aged 29, died, Nov. 12, 1934, of morphine sulphate poisoning self administered.

Ellery Newell Peck & Boonton, N. J., Cornell University Medical College, New York, 1904, served during the World War, aged 55, died Dec. 20, 1934, in the Deaconess Hospital, Brookline, Mass.

James E W Price, Kingston Tenn, University of Tennessee Medical Department, Nashville, 1899, member of the county board of education, also a pharmacist, aged 68, died, Dec. 4, 1934

Patrick H O'Connor, Amboy, Minn., Kansas City (Mo) Hahnemann Medical College, 1906, member of the Minnesota State Medical Association, aged 56, died, Dec. 25, 1934, of heart disease

Gustave Julius Dierkes & Winona, Minn., John A. Creighton Medical College, Omaha, 1917, on the staff of the Winona General Hospital aged 43 died Dec. 9 1934, of pneumonia

Irving S Freeman, Rocky, Okla. Fort Worth School of Medicine, Medical Department of Texas Christian University 1913, aged 49, died, Dec. 27, 1934, in Tulsa of bronchopneumonia

Henry Lee Yoder & Morton Ill., Missouri Medical College, St. Louis, 1899, aged 62, died, Nov. 21, 1934 in the John C. Proctor Hospital, Peoria of prostatic obstruction and pyonephrosis

Joseph P Morris, St. Clair Pa. Jefferson Medical College of Philadelphia, 1896, member of the Medical Society of the State of Pennsylvania, aged 61, died suddenly Dec. 2, 1934

Isaiah Thomas Harbour, Cowlington Okla. Kentucky School of Medicine, Louisville 1888 aged 82 died, January 11, in Fort Smith, Ark., of adenocarcinoma of the pancreas

Martha Louise Dedrick Bayles, Townsend Mont. University of Illinois College of Medicine Chicago, 1930 aged 28, died January 6 in St. John's Hospital, Helena, of septicemia

Hugh Sawyer James, McArthur Ohio, Columbus Medical College, 1890, member of the Ohio State Medical Association served during the World War, aged 69, died, Nov. 15 1934

Clara T Dercum, Philadelphia Woman's Medical College of Pennsylvania Philadelphia 1887 for many years on the staff of the Woman's Hospital aged 76 died, Dec. 23, 1934

John Thomas Deemar, Kittanning, Pa. Jefferson Medical College of Philadelphia, 1879, member of the Medical Society of the State of Pennsylvania aged 80 died, Dec. 9, 1934

James Dennis, Albuquerque N. M., Howard University College of Medicine Washington, 1906 aged 52, died Dec. 23, 1934, of bronchopneumonia following a prostatectomy

Frank Van Rensselaer Phelps, New York, Bellevue Hospital Medical College New York 1893 aged 68, was found dead in his automobile, January 9, of heart disease

Irving Cyrus Blaisdell, Wilmore, Pa., Bellevue Hospital Medical College, New York 1871 aged 90 died, Dec. 12, 1934 of cardiac decompensation and bronchopneumonia.

Louis M Hanemann, New Orleans Tulane University of Louisiana Medical Department New Orleans 1891, aged 65, died, January 8 of cardiovascular renal disease

William Frederick Marten, Ferguson Mo., Hahnemann Medical College and Hospital, Chicago, 1903, aged 46 died Dec. 31, 1934 of a self-inflicted bullet wound

John Anthony Regan, Scranton, Pa., Chicago Medical School, 1934 aged 30 died suddenly, Dec. 27, 1934, in the Scranton State Hospital, of diabetes mellitus

William A Powell, Hernando Miss., College of Physicians and Surgeons Baltimore 1886 aged 72 died January 5 of injuries received in an automobile accident

John Kelly Moeur, Tempe, Ariz. University of Illinois College of Medicine, Chicago 1928 aged 37, died, Nov. 30, 1934, in St. Joseph's Hospital Phoenix

James A Melvin, Baltimore University of Maryland School of Medicine Baltimore 1887 aged 71 died, Dec. 6, 1934 in the Union Memorial Hospital

Abel Mathias Rapid City S. D. University of Pennsylvania School of Medicine Philadelphia, 1865 aged 91 died, Nov. 11 1934 of cerebral hemorrhage

John P Williams, Minneapolis Chicago Medical College 1876 aged 88 died Nov. 11 1934 of coronary sclerosis, arteriosclerosis and chronic nephritis

Augustus F Kempton & Philadelphia Jefferson Medical College of Philadelphia 1880 aged 79 died, Dec. 6 1934 in Ventnor N. J. of chronic nephritis

John Patrick Mulrenan & Philadelphia University of Pennsylvania School of Medicine Philadelphia 1897 aged 64 died January 5 of heart disease.

Samuel Lewis Wilkinson & Belen N. M., University of Arkansas School of Medicine Little Rock 1907 aged 54 died Dec. 30 1934 of angina pectoris

Ephraim Daniel McKenna, Oneonta, N. Y., University of Vermont College of Medicine, Burlington 1887, aged 75, died, January 13, of nephritis

John C Ware, Yellville, Ark., Arkansas Industrial University Medical Department, Little Rock, 1886, aged 85, died, Nov. 5, 1934, of heart disease

George Blatchford, Clinton, Mich. University of Michigan Homeopathic Medical School, 1884, aged 87, died January 2, of chronic myocarditis.

John Duncan, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1906, M.R.C.S., England, 1907, aged 59, died, Nov. 22, 1934

A Marshall Haas, Bunkie, La., Tulane University of Louisiana Medical Department, New Orleans, 1896, coroner, aged 61, died, Dec. 13, 1934

Frank Busby Parker, Ursa, Ill., Keokuk (Iowa) Medical College, 1893, aged 63, died, Dec. 10 1934 in St. Mary Hospital, Quincy, of encephalitis

Simon J Hampshire, Overbrook Kan., College of Physicians and Surgeons, Keokuk, Iowa 1884 aged 74, died, Oct. 31, 1934 of arteriosclerosis

Maurice R Perlstein, Chicago Chicago College of Medicine and Surgery, 1914 aged 43 died, January 21, of hydro-nephrosis and myocarditis

David A Maxwell, Lockesburg, Ark. Memphis (Tenn) Hospital Medical College 1889, aged 78, died, Nov. 18, 1934 of cerebral hemorrhage.

Lewis Augustus Williams, Huntington W. Va., Medical College of Ohio, Cincinnati, 1891, aged 70, died, Dec. 27, 1934, of gastric carcinoma

Michael Joseph Brown, Toronto Ont. Canada, University of Toronto Faculty of Medicine 1920, aged 41, died, Nov. 11, 1934, of heart disease

Henry John Plenz, Chicago, Northwestern University Medical School, Chicago, 1910, aged 46, died January 14, of organic heart disease.

Thomas P W Brooks, Hackleburg Ala. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897, aged 87, died, Dec. 15, 1934

Manassa Thomas Pope, Raleigh, N. C. Leonard Medical School, Raleigh, 1886, died, Nov. 13, 1934 of strangulated hernia and cystitis

John Henry Watson, Toronto, Ont., Canada Victoria University Medical Department, Coburg, 1869, aged 87 died Nov. 16, 1934

William Oscar Sauermann & Houston Texas, University of Michigan Medical School Ann Arbor, 1893 aged 67 died, Nov. 26, 1934

Simon Cameron Bowes, Canonsburg, Pa., Western Pennsylvania Medical College, Pittsburgh, 1893, aged 70 died, Dec. 17, 1934

Everett A Wood, Los Angeles, Keokuk Medical College, 1895, aged 70, died, Dec. 10 1934 in the Los Angeles General Hospital

Napoleon Wagner, Denver, St. Louis College of Physicians and Surgeons, 1884, also a lawyer, aged 76, died Nov. 15, 1934

Charles Mikula, Dwight, Kan. (licensed in Kansas in 1901) aged 72, died Dec. 14, 1934, of carcinoma of the stomach

Geoffrey Boyd, Toronto, Ont. Canada University of Toronto Faculty of Medicine, 1891, aged 65, died, Dec. 22, 1934

James Archibald Hamilton, Winnipeg Manit. Canada Manitoba Medical College Winnipeg, 1904 died, Dec. 26, 1934

Dennis P Russell Chicago, Rush Medical College, Chicago, 1890, aged 74, died January 15, of cirrhosis of the liver

Thomas Nathan Eblen, Orme Tenn. Chattanooga (Tenn) Medical College, 1899, aged 62 died, January 5, of pneumonia

Robert S Medearis, North Little Rock, Ark. (licensed in Arkansas in 1903) aged 64 died Dec. 8, 1934

John G Chessher, Falco, Ala. Chattanooga (Tenn) Medical College 1901 aged 76, died Nov. 17, 1934

Bureau of Investigation

AMERICAN INSTITUTE OF MEDICINE AND SURGERY, INC

An Impudent Scheme Designed to Capitalize the Vanity of Physicians and Others

In December, 1934, news items began appearing in newspapers—usually those published in the smaller towns—regarding an alleged "honor" that had been conferred upon some local citizen by the "American Institute of Medicine and Surgery" at a meeting of the "nominating committee" in New York. Such local celebrities appeared at first to be mainly optometrists, although the list has since been extended to cover osteopaths and physicians.

Following the appearance of the local news item, the person whose name was mentioned would receive a letter informing him in detail of the alleged honor and asking him to sign a "pledge" that is enclosed, and to return it with a check or money order for \$25 on receipt of which the American Institute of Medicine and Surgery would send a handsome certificate for framing and hanging in the reception room.

Some of the members of the American Optometric Association, recognizing that as they practice neither medicine nor surgery the alleged honor that was said to have been conferred on them was obviously undeserved, questioned the bona-fides of the imposingly named "Institute." As a result, the *Optometric Weekly* published in its issue of Dec. 27, 1934, a warning item entitled "Look Out for This Racket."

This probably interfered with the success of the scheme among optometrists and may explain why osteopaths and physicians were then worked on.

The news items already referred to have appeared in various parts of the United States ranging from Florida to California. The letter that the individuals whose names were published in the local papers received from the so-called American Institute of Medicine and Surgery, Inc., of 150 Nassau St., New York City, read as follows:

Dear Doctor—It is my privilege to announce that the Board of Directors has qualified you for a life-time honorary membership in the American Institute of Medicine and Surgery. This is to take effect upon your signing the inclosed pledge and fulfilling the usual preliminary requirements of honorary membership.

Because the American Institute of Medicine and Surgery is a non profit making corporation there are no annual dues. One initiation fee of Twenty five dollars (\$25.00) alone is required from each honorary member.

Please sign your name to the inclosed pledge and print your name plainly below in the form you wish it to appear on the Certificate of Honorary Membership a facsimile of which is printed on the pledge. The Certificate as it is sent to you is 14 inches by 17 inches in size and may be framed and hung in the reception room of your office thereby showing to whom it may concern that you have been signally honored by this organization.

We heartily congratulate you upon your selection as an outstanding representative of your profession in your district and trust that you will at your earliest convenience return the pledge properly signed together with check or money order to cover the initiation fee.

Accompanying the letter, which was signed 'John J. Caldwell Secretary,' was a miniature reproduction of the "certificate of honorary membership" for which the optometrist, osteopath or physician was asked to send \$25, there was also the 'honorary membership pledge,' which the recipient was asked to sign and return with his \$25.00. The "pledge" read as follows:

I pledge myself to maintain the highest ethics of my profession and to do all within my power to bring a new era of physical and mental well-being to the peoples of the world.

WITH TRUE APPRECIATION of the dignity nobility and sacrifice of this my life work I sign my name to this pledge.

There was the inevitable dotted line just below the 'pledge' for the signature of the person to whom it was sent. The 'certificate' itself is reproduced with this article, in order to

give a general idea of the character of the piece of paper for which physicians and others are expected to pay \$25. Because of the great reduction in size made necessary by the limitations of space, the wording of this certificate is here reproduced.

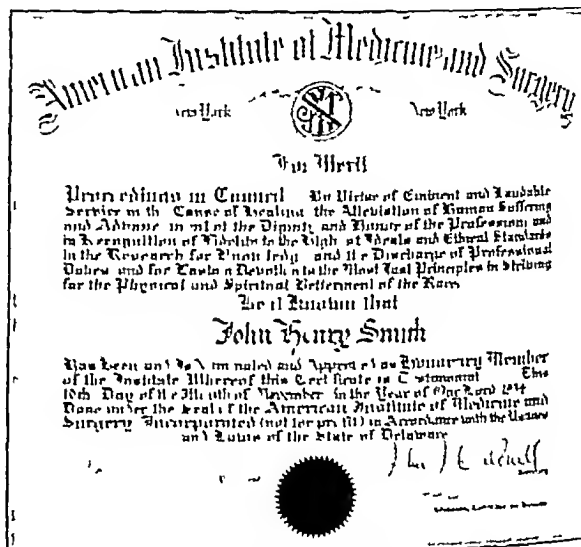

'Proceedings in Council By Virtue of Eminent and Laudable Service in the Cause of Healing the Alleviation of Human Suffering and Advancement of the Dignity and Honor of the Profession and in Recognition of Fidelity to the Highest Ideals and Ethical Standards in the Research for Knowledge and the Discharge of Professional Duties and for Lasting Devotion to the Most Just Principles in Striving for the Physical and Spiritual Betterment of the Race,

Be it known that

JOHN HENRY SMITH

Has Been and Is Nominated and Approved as Honorary Member of the Institute Whereof this Certificate is Testimonial. This 10th Day of the Month of November in the Year of Our Lord 1934 Done under the Seal of the American Institute of Medicine and Surgery Incorporated (not for profit) in Accordance with the Usages and Laws of the State of Delaware

The certificate is signed by the "President," "Secretary" and "Chairman, Committee on Honors." As well as can be deciphered from the reproduction sent out, the president's name appears to be Robert V. Steele the secretary's John J. Caldwell.

Reproduction (greatly reduced—the originals are 14 inches by 17 inches) of the Certificate of Honorary Membership which the "American Institute of Medicine and Surgery, Inc." attempts to sell to optometrists, osteopaths and physicians for \$25.00. The alleged institute does not exist except on paper. What the certificate actually certifies to is that the possessor is on easy mark or a poseur.

—whose name also appears in connection with the letter—and that of the chairman of the "Committee on honors" [1] E. L. Fogelsonger.

The American Institute of Medicine and Surgery, Inc., was not to be found in any record possessed by the Bureau of Investigation, it was obviously a new humbug. Neither did one find the names of Steele, Caldwell or Fogelsonger.

From investigation it appears that the so-called American Institute of Medicine and Surgery, Inc., is a New York organization incorporated in November, 1934, with no stated authorized capital, that Fogelsonger is the dominating factor in the enterprise and that he is alleged to have formerly been financially interested in the "Book Craft Guild"—whatever that may have been—said to have been established in April 1932, but now to be out of business. The headquarters of this imposingly named outfit were simply rented quarters in Room 736 in the office building at 150 Nassau Street. Efforts to obtain an interview with Fogelsonger were fruitless, and no one could be found who either had or was willing to furnish information on which an estimate of the responsibility of the concern could be determined. Further help was sought through both the National Better Business Bureau and the Better Business

Bureau of New York City The latter organization reported that the post-office officials were investigating and that both Caldwell and Fogelsonger had disappeared It reported, also, that Ann Lord, a reputed publicity agent at 53 Park Row, had a mailing address there, but her identity was unknown

A search of the files of the Bureau of Investigation failed to show any record of any "Ann Lord" as a publicity agent There was a record of one Annie Lord, who has sometimes, it appears gone by the title Dr In 1933 there was one Annie Lord who called herself a "Consulting Psychologist" operating from Studio 603 Carnegie Hall, New York City Then there was an Annie Lord whose advertisement was published in the *Chicago Tribune* April 17, 1932, in which the lady was described as an "Eminent Business Analyst of Washington, D C" The Bureau also has a record of one Annie Lord, a "naturopath," who in 1928 was prosecuted and found guilty of practicing medicine without a license by the state authorities of New Jersey A news item to this effect was published in *THE JOURNAL* July 28, 1928 None of these Annie Lords, however, seem to fit in with the Ann Lord referred to by the Better Business Bureau of New York City In fact, a later letter from that organization reported that the current telephone directory of New York City carried the name "Annie Lord, Psychic" at 210 West 72d Street

As the "certificate" of the American Institute of Medicine and Surgery definitely states that the concern is a Delaware corporation, the Bureau of Investigation asked the Secretary of State of Delaware, for the names of the officers and incorporators The secretary replied on January 16 1935 that (1) the "institute" was incorporated August 6 1934, but the annual report showing the names of the officers had not yet been filed (2) the Capital Trust Co of Delaware was the resident agent and (3) the incorporators were Robert V Steele, 2449 28th St., Astoria, L I, N Y John J Caldwell 68 East 90th St., New York City Fogelsonger (no given name or initials), 165 W 87th St., N Y C

The Better Business Bureau of New York City reported further, that on January 21 Post Office Inspector Frank Shea had instructed Fogelsonger to call at his office, at which time a representative of the Better Business Bureau of New York City was present The entire matter was submitted to Mr Pfann, Assistant United States Attorney, who, after reviewing the facts, is reported to have told Fogelsonger that while there was not at present sufficient evidence to warrant prosecution for a mail-order fraud, Fogelsonger, Caldwell and Steele were heading for trouble None of the three men back of the scheme are physicians or have any interest in the medical profession—other, presumably than the effort to get \$25 from certain members of that profession

The scheme is not original Nearly forty years ago a quack named Probert sold from Niles Michigan, so called 'Certificates of Merit' from the fake 'St Luke's Hospital' of that city After the Michigan legislature outlawed this swindle the name and locality was changed and it became the 'Christian Hospital' of Chicago A quarter of a century ago many of these 'certificates' adorned the walls of advertising quacks Then there was the imposingly named Incorporated Society of Science Letters and Art of London an English swindle that sold Fellowships to all and sundry at one guinea (\$5 00) apiece These permitted the owners to write the mystic letters 'F S Sc.(Lond)' after their names which many American patent medicine exploiters did In Italy there was the Italian Physio-Chemical Society of Palermo which sold diplomas at \$500 and 'First Class Medals for Technical Work and Scientific Merit' for \$1000 to vainglorious or gullible Americans

One needs waste no sympathy on physicians, osteopaths or optometrists who have parted with \$25 00 for the gaudy piece of paper sold by Messrs Steele Caldwell and Fogelsonger and obviously designed to deceive the public and appeal to the vanity of the purchasers It is obvious that membership in American Institute of Medicine and Surgery, Inc., simply means that the member is either an easy mark or a poseur who would assume an erudition he does not possess or both

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

DETERMINATION OF HEMOGLOBIN

To the Editor—There has been a considerable amount of controversy regarding the determination of hemoglobin At the present time I am using the improved Sahli instrument graduated in per cent and in grams per hundred cubic centimeters, 145 Gm per hundred cubic centimeters being the equivalent of 100 per cent It has also been my practice to estimate the color index by using percentage rather than Sahli units The latter were used on the tubes formerly supplied and having a circular cross section It is claimed that my hemoglobin determinations are too high and that Sahli units should be used for this purpose Just what does a Sahli unit indicate? I am anxious to know this particularly because I am contemplating the purchase of a new instrument Please omit name

M D New York

ANSWER—Much of the controversy that exists regarding the determination of hemoglobin is due to the method employed or the manner in which the results are expressed There are now on the market several accurate hemoglobinometers that may be conveniently used for office practice Unless these have been carefully checked before leaving the factory, however, inaccuracies may arise Errors in the bore and graduation of the tube and pipet may contribute to wrong values Despite the precaution in providing an accurate instrument, discrepancies may arise also in the manner of expressing hemoglobin values Formerly hemoglobin was expressed by an empirical scale of per cent and Sahli units For example, the old Sahli tube had a scale showing Sahli units and opposite this was a per cent scale for those who prefer to express their results by this designation The 100 per cent mark was opposite 80 Sahli units These two readings had a value of 17 Gm of hemoglobin per hundred cubic centimeters of blood Different hemoglobinometers also graduated in per cent gave different values on the same sample of blood The confusion lay not in the method of determination but in the lack in agreement as to how many grams of hemoglobin constituted 100 per cent As an illustration of this situation the following values have been suggested as being equal to 100 per cent Dare (new), 160 Gm, Haldane, 138 Gm Tailqvist, 158 Gm, Haden 156 Gm, Osgood, 146 Gm, and Wintrobe, 145 Gm Obviously, unless one knew the method by which per cent was determined and reduced to a common factor such as grams per hundred cubic centimeters of blood, there would be considerable disagreement even on the same sample of blood Because of the potential confusion when values are reported in per cent without stating the standard on which it is based, it has been urged that hemoglobin be reported in grams per hundred cubic centimeters of blood Theoretically, this would avoid confusion regardless of what instrument is used Practically, however, there are still discrepancies, because the various methods are not all carefully standardized and accurate, and errors in technique also may arise Therefore, it is best when purchasing a hemoglobinometer to find out whether it has been carefully checked against the Van Slyke oxygen capacity method or the more accurate methods for iron determination and standardized It should also be as free as possible from any potential technical error The instrument that the correspondent has is satisfactory The new Heilige Sahli is based on the recent work of Dr M M Wintrobe and has been carefully checked and standardized Because of the preference of some clinicians still to express hemoglobin in per cent, the tube is graduated in per cent as well as in grams When the hemoglobin is expressed in per cent, 145 Gm is used as the equivalent of 100 per cent While the adoption of this value for 100 per cent gives a reliable color index it yields high percentages for most adult males The reason for this is that the hemoglobin values for normal male adults average about 16 Gm per hundred cubic centimeters of blood, with from 14 to 18 Gm as the limits of normal adult women average 14 Gm, with a normal range of from 12 to 16 Gm It is therefore preferable to express hemoglobin values in grams rather than in per cent It may be that the correspondent's values are too high because he reports them in per cent based on 145 Gm of hemoglobin per hundred cubic centimeters of blood as being equivalent to 100 per cent If this is not the case it is advisable to make sure that the hemoglobinometer has been properly standardized

ECZEMA OF AUDITORY CANAL

To the Editor—A woman, aged 30 has chronic eczema of the external auditory canal of both ears. There is a constant desquamatum with considerable amounts of creamy moisture that has an unpleasant odor. There is intense itching and it is almost impossible for the patient to refrain from rubbing the mucous membrane either with a twisted handkerchief or with a toothpick applicator. On thorough cleansing there is no abnormality except a slight thickening and marked redness of the lining of the canal. There are no foci of infection; the patient is perfectly healthy in every respect except that she may be hypersensitive to the slight odor of this nasal discharge. The discharge is not excessive but if it is allowed to remain for a few days the canal becomes partially filled with moist creamy looking scales which produce a fetid odor. Under daily cleansing treatment the canal remains clean but after two days or more the condition constantly recurs. I have tried every form of treatment that I have access to such as boric acid powder insufflation, metaphen applied topically and by the pack method, quartz light treatment, salicylic acid in collodion painted on the mucosa, phenol and glycerin and hydrogen dioxide and all that has been accomplished is a temporary relief from symptoms. Even when the patient leaves the canal strictly alone a discharge and moist appearance of the mucosa will occur. I should like to know what more I can do for this woman. Please omit name.

M D Illinois

ANSWER.—The quickest and clearest method of giving relief would be roentgen rays, one-fourth erythema dose once a week. If this is not available, solution of aluminum acetate 1 part to 16 parts of water, may be applied on a roll of cotton or gauze. When this has succeeded in stopping the discharge, 1 per cent salicylic acid and resorcinol in 30 per cent alcohol should be swabbed on frequently and allowed to dry on. The patient must refrain from scratching or rubbing or the condition will not clear up. She should apply the lotion when tempted to scratch.

After the surface has ceased to weep gentle applications with a swab, once or twice a day, should be made of rectified oil of birch tar, 0.8 cc, resorcinol 0.4 cc, and liquid petrolatum sufficient to make 16 cc. If this causes oozing or increased itching, it cannot be used. For soothing 10 per cent boric acid in petrolatum should be used. If oozing recurs the solution of aluminum acetate treatment should be resumed. If improvement ceases after a considerable use of the oil the strength may be doubled or ointment of rose water containing 5 per cent of coal tar solution and 2 per cent of salicylic acid may be substituted. For cleansing oil or liquid petrolatum may be used. It must be expected that the dermatitis will return after a time. A definite cure of such a condition is hard to promise.

SINUS INTO ANTRUM

To the Editor—About a year ago a man aged 55 had a tooth extracted and an infection of the antrum developed. There were the usual symptoms of pain and purulent discharge for which he did nothing until several weeks elapsed and then I saw him though only for a few times as he thought that he could care for himself. Now he comes with a sinus that is quite open, with a little discharge and expects it to be healed in a short time. Will you please give me the best treatment for it? Will irrigations do any good and also is curettement of the antrum indicated? Kindly omit name.

M D Minnesota

ANSWER.—The fistula that occasionally develops after extraction of a tooth the root of which extends to or into the maxillary sinus is often resistant to treatments so far as closure is concerned. If there is a change in the mucosa of the antrum it would be necessary to operate either intranasally or by way of the canine fossa, removing all diseased tissue, freshening the edges of the fistula, and suturing. In some cases in which the changes in the antrum are not definite a few irrigations followed by freshening of the edges of the mucosa of the fistula, and suturing, may suffice. In other cases it is impossible to approximate the edges of the mucous membrane without making a flap in order to effect the perfect closure of the opening leading into the antrum.

INTELLIGENCE OF CHILDREN WITH CONGENITAL SYPHILIS

To the Editor—In THE JOURNAL Nov 24 1934 appears the statement for they are frequently somewhat above the ordinary in intelligence, in a query and minor note entitled Child with Congenital Syphilis. It will be appreciated if you will kindly extend the statement to detail.

EDGAR C. HAYHOW Paterson N J
Superintendent Paterson General Hospital

ANSWER.—A statement regarding precocity in children with congenital syphilis deserves emphasis because of the tendency among the uninitiated to regard congenital syphilis as a principal cause of imbecility, feeble-mindedness, idiocy, backwardness and mental retardation. White and Vieder in 443 cases found

157 per cent of mental retardation, including all grades from idiocy upward. The milder grades seem much the more common. In Stokes's series, 25 per cent were below par mentally as expressed by slow progress in school and difficulties in adaptation. Twenty-two per cent of his patients exhibited heightened nervous irritability with emotional instability, fits of temper, night terrors, the easy development of tics and habit spasms, and the like. Twelve per cent of Stokes's series exhibited a mental development well beyond their years. In many cases, in spite of the handicaps of eye trouble and susceptibility to other illness it was quite sufficient to place them well beyond the average in school. The Solomons call attention to the precocity observed in certain syphilitic children, with citation of a case illustration but properly emphasize that this precocity does not indicate that syphilitic heredity is an asset but that the disease had no effect on this child's mentality. The general studies of Haines and of Bazeley and Anderson do not greatly clarify the problems of conduct disorder with which they deal in relation to syphilis but support the general view that the disease may markedly influence abnormalities in this field.

It is apparent, therefore, that the mental and nervous state of children with congenital syphilis may vary between idiocy and precocity and that a sharp distinction must be drawn between the coincidence and the possible etiologic association between the syphilis and the mental state. At least it can be definitely shown, and is familiar to all syphilologists of experience, that a high degree of precocity is in no way inconsistent with the presence of a congenital syphilitic infection.

POSITION OF HEAD IN TONSILLECTOMY

To the Editor—I should like to know whether it is feasible to have a patient during a tonsillectomy tilted head down at an angle of about 10 degrees. The most frequent serious complication of tonsillectomy is lung abscess due to aspiration during or shortly after the operation. The article by Smith (THE JOURNAL, September 29 p. 971) in which he stated that in thirty-nine cases of lung abscess thirteen followed tonsillectomy prompted my query. Murphy (Am. J. Obst. & Gynec. 27: 118 [Jan.] 1934) has shown that in curarized cats kept alive in a respirator and tilted head down at an angle of from 15 to 20 degrees, fluid dropped into the trachea was not aspirated into the lungs. Probably the tendency to aspiration is greater in a respirator than during anesthesia when breathing is shallow. For that reason a patient might be tilted only 10 degrees or so to avoid aspiration. It may be that some surgeons do tilt their patients during tonsillectomy but I have seen only one do so and that was Dr. Sullivan of Mount Vernon. There may be some objection to such a procedure which I do not realize but it seems a simple prophylactic measure. After the operation the patient's bed could be tilted head down until he regains his cough reflex.

M. BERNARD BRANDY M D Mount Vernon N Y

ANSWER.—It would seem that there is no contraindication whatever to having the head tilted down when tonsillectomy is performed under general anesthesia. Many years ago the late Dr. F. Gurney Stubbs did all his operations in this manner without any difficulty so far as any postoperative complications were concerned. With the head tilted down, he and many other good operators were in the habit of sitting directly behind the patient instead of to one side, as is ordinarily done while the head lies flat on the table.

MANAGEMENT OF THYROID CRISES

To the Editor—I am particularly interested in the use of compound solution of iodine (Lugol's solution) by the intravenous route both in thyroid crisis and as a routine procedure following thyroidectomy for hyperthyroidism. Has this method of administration been used to any extent and if so is there any literature to which I can refer? Please omit name.

M D New Jersey

ANSWER.—The questions suggest that the inquirer believes that compound solution of iodine is a unique and necessary formula for the administration of iodine to patients with hyperthyroidism. Many studies now prove that iodine in whatever form is the effective agent. It is not necessary, therefore, to give compound solution of iodine intravenously as a matter of fact its chemical nature prohibits such usage. Potassium iodide in concentrated sterile solution—from pharmaceutical ampules—or diluted in other fluids—given by venoclysis may be given intravenously during thyroid crises. However, the instantaneous absorption of iodine from the gastro-intestinal tract makes the parenteral route unnecessary. A diluted compound solution of iodine may be given into the corner of the mouth with a medicine dropper, 136 cc (200 minims) a day of compound solution of iodine may thus be given. Examples of the management of thyroid crises are given by Paul Starr (The Course of Hyperthyroidism under Iodine Medication, Arch. Int. Med. 39: 520 [April] 1927).

HEART DISEASE

To the Editor—Mrs A aged 27 married nine years has no children. The childhood history is negative except for tonsillar infections. The latter were treated subsequently by the electrocautery at the time of the cardiac infection. Several weeks after her marriage about nine years ago after having a subacute throat infection she was suddenly taken ill with cardiac collapse characterized by arrhythmia and extrasystoles. She was not then under my care, but the history of that illness was one of long duration (about nine months), little or no fever at onset with negative blood cultures and throat cultures. The last three months included invalidism continued osthenia and extrasystoles. The bearing of children was not advised. Since that original illness she has always experienced missing heartbeats with greater or less frequency never being entirely free from them for more than some hours. Since then she has had several periods a year of acute relapse being bed ridden for weeks at a time suffering from missing heartbeats and shortness of breath the extrasystoles then always being accompanied by severe shock and a dry, hacking cough. I first treated the patient last spring when she went through a relapse lasting about six weeks. When she is feeling comparatively well and strong the extrasystoles though they occur are not accompanied by cough dyspnea or shock. But when she has a relapse the missing heartbeats are extremely exhausting and the patient coughs continuously. She may have a period of feeling very well and without any exciting cause her heart becomes bad and she commences to cough. The patient is well nourished and otherwise normal. The tonsils are now small and she rarely suffers from sore throats. The electrocardiogram taken several times is entirely normal as the extrasystoles disappear apparently when the pulse reaches about 100 as a result of nervous excitement. Ordinarily her pulse is between 70 and 80. Sedatives have an uncertain action as well as digitalis. Roentgen examination shows only a slightly enlarged heart. The lungs are normal. There are no cardiac murmurs. Even under morphine I have seen her cough and the heart miss for six to twelve hours. I would appreciate therapeutic suggestions and discussion of this case. Kindly omit my name in publishing.

M D New York

ANSWER—Heart disease at the age of 27, with the history of cardiac infection at the time of or following tonsillitis, suggests that this case is an example of chronic rheumatic carditis. This condition complicated by subacute bacterial endocarditis may well be the explanation of the continued invalidism and periodic acute exacerbations even though blood cultures have been negative. Low fever or its absence would not exclude this possibility nor would the failure to observe embolic phenomena or splenic enlargement entirely remove the possibility from consideration.

However, from the description of the relapses, with dyspnea and cough, it would be easy to believe that recurrent congestive heart failure with passive congestion of the lungs is the cause. This of course, is frequent in mitral stenosis. A disorder of cardiac mechanism such as paroxysmal auricular fibrillation might be responsible.

It is unlikely that extrasystoles in a normal mechanism would cause such a picture even though they occur with great frequency. The fact that the patient complains of the heart missing suggests heart consciousness. Neurotic individuals frequently complain of extrasystoles even when there is no other impairment of cardiac function. On the other hand, many people who have frequent premature contractions either are unconscious of them or at least offer no complaint.

Digitalis is not indicated unless decompensation is present or imminent because its effect on heart muscle irritability will increase the frequency of extrasystoles. Sedatives have relatively little effect on premature contractions. Quinidine might be useful but only too often even in large doses, it will not alter this type of arrhythmia. It is noted that increase in heart rate causes the rhythm to become regular. If there is no contraindication to its use and extrasystoles are the main cause of complaint, desiccated thyroid in cautious doses may be helpful by increasing the heart rate to the point at which the arrhythmia disappears.

BED SORES

To the Editor—A white patient aged 28 had a fracture of the spine at the junction of the twelfth dorsal and first lumbar vertebrae with a resulting paralysis. A body cast was applied for two months and as a result large bed sores formed over the great trochanters of each femur and over the area of the sacrum. These sores are cleansed each day with alcohol and zinc oxide ointment is applied. The patient is given a balanced diet and insulin daily. Healing has been very slow. What suggestions have you for the treatment of these bed sores? This patient is at home and hospitalization is out of the question because of the family's economic condition.

ADRIAN B CAIRNS M D Pollock, La

ANSWER—It is advisable to discontinue the daily cleansing with alcohol as this might kill the new growth of cells. The ulcers probably require stimulation, for which purpose balsam of peru is the time honored remedy. It may be applied full strength or mixed with castor oil in whatever proportion is required to subdue the burning sensation produced in the more sensitive ulcers. Especially stimulant to the growth of

epithelium is scarlet red ointment (5 per cent) which might be applied on days alternating with the balsam of peru dressing. Thucresol compresses have of late been advocated to stimulate healing of very extensive ulcers. A freshly prepared 1:10,000 solution (of the 2 per cent alcoholic stock solution, 5 cc is mixed with 100 cc of distilled water) is applied on gauze which is then covered with waterproof material. This dressing is changed every two hours. To avoid excessive irritation, it is best alternated with compresses of physiologic solution of sodium chloride at possibly forty eight hour periods. Skin grafting should be undertaken for all large ulcers as soon as a bed of healthy granulations has been secured, and the modern method of "seed implants" is so simple and uniformly successful that there should be no hesitancy in resorting to it promptly.

USE OF WHOOPING COUGH VACCINE

To the Editor—I have attempted recently to immunize a number of children against whooping cough. I have used a vaccine manufactured by Squibb & Sons which is claimed to contain 10,000 million bacilli (*Haemophilus pertussis*) per cubic centimeter. The literature accompanying the vaccine recommends a dose of 0.5 and 1 cc, at intervals of about five days irrespective of age. I have given the children 0.5 and 1 cc subcutaneously at five day intervals and have had a number of rather severe general and local reactions. The reactions consist of fever, nausea, vomiting, diarrhea, malaise and occasionally a cough. The local reactions consist of redness, swelling and pain. I would appreciate an opinion of the following questions: Does the present status of pertussis vaccine warrant its use as an immunizing agent? Would the use of the higher dosage as recommended be likely to give rise to reactions of a serious nature? Please discuss accepted dosage. Kindly omit name.

M D New York

ANSWER—The Council on Pharmacy and Chemistry omitted in 1931 all pertussis vaccines from New and Nonofficial Remedies because in twenty years no conclusive evidence had been accumulated regarding the therapeutic or prophylactic efficacy of such preparations. Recently Sauer (Whooping Cough. A Study in Immunization. *THE JOURNAL*, Jan 28 1933, p 239. Immunization with Bacillus Pertussis Vaccine. Nov 4 1933 p 1449) has brought the first convincing evidence that his vaccine, prepared from recently isolated, hemolytic strains, of the pertussis bacillus grown on medium prepared with human blood, will confer prolonged immunity in a high percentage of young children if injected at least several months before exposure. This vaccine is now available (Lilly's V 374 Parke Davis Bio 204). A total of 8 cc (1, 1.5 and 1.5 cc, bilaterally) is given hypodermically in the course of three successive weeks. Prepared without alien blood, local and systemic reactions when they occur are seldom severe and have never been serious in the seven years that it has been in use.

NEPHROPTOSIS AND URETERAL STRICTURE

To the Editor—A white American woman aged 31 a teacher was laid up to the hospital for six weeks in May and June with an attack of acute bilateral pyelitis of *Bacillus coli* type. Last week a pyelogram was taken and it showed a general visceral ptosis especially involving the left kidney. The left ureter was kinked and bound down and near the pelvis of the kidney it was narrowed. It is being dilated now and a kidney belt has been ordered from the United States. The urologist intends to dilate the ureter about four or five times. What I want to know is this: Are there any exercises that will tend to hold the kidneys in place? Are there any postural treatments that will supplement the action of the kidney belt and in time enable the patient to do without a belt which is rather hard to wear to a tropical climate? The patient is 5 feet 6 inches (168 cm) tall and weighs 130 pounds (59 kg). She has always been an active girl swimming riding horseback and bowling. Her musculature is good. Please omit name.

M D Canal Zone

ANSWER—There is no postural treatment that is of definite value in nephroptosis. It must be kept in mind however, that patients must be instructed to apply the kidney belt while they are recumbent and not while they are standing. As a general rule, patients with nephroptosis are underweight. The administration of a high caloric diet is indicated to increase the patient's weight particularly to add to the renal fat. This may assist materially in the elimination of symptoms. The more strenuous exercises such as riding horseback and bowling, should be avoided but swimming may be permitted.

It is unusual for a patient to have both nephroptosis and ureteral stricture. In most instances the narrowing and kinking of the ureter is only an apparent one which is the result of faulty technique in making the pyelogram. Unless there is evidence of back pressure such as dilatation of the renal pelvis and calices, it would be well to review the diagnosis.

The use of the ketogenic diet to eliminate the infection with colon bacilli may be all that is needed and continued use of the belt might become unnecessary.

ADENOMA IN THYROID AND EFFECTS ON
HEART MUSCULATURE

To the Editor—Question has arisen locally as to whether the presence of an adenoma of the thyroid gland whether associated with increased metabolic rate or not existing over a period of years should be a source of danger to the heart musculature. The question has arisen regarding a case in which a man is known to have had an adenoma of the thyroid gland over a period of twenty years and who in the last two or three years has developed cardiac decompensation. Lacking a specific cause I wonder whether this adenoma although causing no increase in metabolism may not have been the underlying factor. I would appreciate your letting me have whatever references may appear in the literature on this subject.

J. STUART STALEY, M.D. Marion, Va.

ANSWER—An adenoma of the thyroid gland associated with an increased metabolic rate is regarded by all observers as a cause of cardiac embarrassment. It is doubtful whether any form of thyroid disease of itself produces significant permanent organic changes in the heart muscle, or congestive heart failure. When the latter developments are found, there is almost always an additional and independent form of heart disease such as a valvular hypertensive coronary artery or syphilitic process. Symptoms such as fibrillation, palpitation, dyspnea and weakness, however, can occur as a result of the thyroid disease alone. It is unlikely that an adenoma unassociated with toxicity or an increase in the metabolic rate is a significant danger to the heart musculature. But finding the basal metabolism within normal limits is no proof that it always has been normal and plus 80 per cent may be 20 per cent above that patient's normal rate if he started from a minus 12 per cent. Furthermore there are certain "toxic" effects that are supposed to be due to the thyroid gland that are independent of the metabolic rate and may be going on when the metabolic determinations are normal. USE OF PITUITARY PREPARATIONS FOR
INCREASING GROWTH

To the Editor—Recently a well nourished girl of 12 asked me what I could do to increase her stature which is decidedly short for her age. She is quite bright and does not complain of cold weather, so I did not have her basal metabolism taken. I know that pituitary preparations are sometimes used for this purpose but should like further information as to the method of administration by mouth or otherwise, dose, method of control and efficiency and general advisability. Kindly omit name.

M.D. Colorado

ANSWER—It is not possible to determine the precise nature of the growth disturbance in this case. If it is assumed, however, that the patient is suffering from hypopituitarism (and it is known from animal experiments that the anterior lobe of the pituitary gland exercises control of bodily growth, particularly on bone development) the treatment of this child may be considered through the use of pituitary substances. The use of the dried anterior pituitary gland given by mouth, even in large doses has usually failed to produce any results. Evans in 1921 showed that the simple watery extracts of the anterior pituitary glands of oxen injected into rats caused acceleration of growth. Later on, one of Evans's students working in Cushing's Laboratory at Harvard produced experimental acromegaly as well as an increase in size of the internal organs by injecting into dogs products containing the anterior pituitary growth hormone. A similar preparation may be given hypodermically in doses of 1 cc. daily. The preparation made by E. R. Squibb and Son containing the anterior pituitary growth hormone has been administered in doses of from 7 to 15 minims (0.4 to 0.9 cc.) intramuscularly once daily. Engelbach and Schaefer (*THE JOURNAL*, Aug. 18, 1934, p. 464) have treated seven cases of endocrine dwarfism by using the solution of the pituitary growth factor marketed by Parke, Davis & Co. under the name "antuitrin-G." They injected 2 cc. of this substance three times a week and report that no untoward results were noted at any time. The increase in height varied from 1 to 2 7/10 inches. These patients were from 7 to 18 years of age. They were under observation before treatment from four to six months and under treatment with antuitrin-G from three to five months. These investigators found that the addition of thyroid extract was a valuable adjunct in the treatment. The improvement was indicated not only by increase in height but also by roentgen examination of the bones, which showed an advance in osseous development.

In the use of these remedies one should not be oversanguine as to results. The writer of the query is advised to read the editorial contained in *THE JOURNAL*, August 18, "Antihormones," which emphasizes that antihormones may be produced in the body by the administration of endocrine substances and indicates the advisability of utmost caution in their clinical use.

PREVENTION OF HEMORRHAGE IN CESAREAN
OPERATION

To the Editor—In doing a cesarean section what medicine is usually injected to prevent uterine hemorrhage? I understand that solution of pituitary and ergot are usually employed. Should they be injected together? How long does it take for them to work ordinarily? Should they be injected into the uterus or subcutaneously or intramuscularly? If the solution of pituitary starts to act as the incision is started in the uterus is there any likelihood of its causing such fast or strong contraction of the uterine musculature that the uterus will tear by its own contraction? The work is being done under spinal anesthesia. Please omit name.

M.D. Texas

ANSWER—Obstetricians who employ solution of pituitary and ergot to prevent uterine hemorrhage in cases of cesarean section generally give 1 cc. of ergotamine tartrate, or Gynergen, hypodermically just before the operation is begun and 1 cc. of solution of pituitary immediately after the baby is extracted from the uterus. Both injections are usually given intramuscularly in the deltoid muscle. However, not infrequently the solution of pituitary is injected directly into the uterine musculature a sterile needle being used, of course. This method produces much more prompt contractions of the uterus. Often the uterus becomes contracted and blanched within one minute after the injection. When the solution of pituitary is injected into the arm the uterus usually contracts within two or three minutes. The general belief is that the effect of ergot does not become manifest for from fifteen to twenty minutes, hence this drug is given before the operation is begun.

Recently there has arisen doubt about the potency of hypodermic preparations of ergot, some investigators maintaining that such preparations have practically no effect on the uterus. There is, however, almost unanimity of opinion concerning the fact that fluidextract of ergot, as administered by mouth, has a definite stimulating effect on the uterus. Hence ergot may be given by mouth before a cesarean section, especially if local anesthesia is to be used. If solution of pituitary is given before the baby is delivered the uterus may contract so markedly that there will be difficulty in extracting the child. The uterus, however, will not tear unless the operator attempts to deliver the child forcibly.

Spinal anesthesia will not inhibit the effect of pituitary extract on the uterus. However, as has been pointed out by a number of observers, spinal anesthesia is much more hazardous for pregnant than for nonpregnant women. Whenever possible, direct infiltration anesthesia should be used instead of spinal anesthesia, because it is simple and much safer than spinal anesthesia.

SPINAL FLUID EXAMINATION IN SYPHILIS

To the Editor—I should like to know the consensus on the interpretation of the spinal fluid examination in the different forms of syphilis with the presence and absence of the characteristic laboratory observations, including the blood Kahn and Wassermann tests. I am particularly interested in whether a diagnosis of dementia paralytica could be made on the finding of a paretic curve with a negative spinal Wassermann reaction, a positive blood Wassermann reaction and normal cells. Ross, Jones and Pandey. The diagnosis of dementia paralytica in this particular case was disputed despite the fact that the clinical picture would fit that of dementia paralytica. Kindly omit name.

M.D., Chicago

ANSWER—Spinal fluid changes may occur in the primary and secondary stages of syphilis but are most pronounced and of highest diagnostic value in the late stages of the disease.

In the latter, however, the blood Wassermann and Kahn tests may give positive reactions with no abnormal changes in the spinal fluid. However, just the reverse may occur with pronounced spinal fluid changes of pleocytosis, increase of protein, positive Wassermann reaction and a colloidal gold curve (usually of the zone II type) when the blood tests give negative reactions. Such usually occur in cases of asymptomatic neurosyphilis but constitute a very important reason for the routine examination of the spinal fluid in cases of chronic syphilis, and particularly before treatment is stopped, to prevent the regrettable mistake of undertreating the disease.

Unfortunately, the colloidal gold test is subject to error because of difficulties in the preparation of the reagent. In the case cited the spinal fluid gave a paretic curve (zone I) with a negative Wassermann reaction, normal cell count and no increase of protein. Under these conditions the question of probable dementia paralytica must be questioned since in this

type of neurosyphilis the Wassermann reaction by an acceptable method is almost invariably positive along with pleocytosis and increase of protein. It would be hazardous to conclude that dementia paralytica is present on the basis of the colloidal gold reaction alone because of the chances of technical error referable to the reagent, which may precipitate if the gold is insufficiently "protected."

On the other hand the colloidal gold test with a proper reagent is of high diagnostic value but curves of precipitation are associated with positive Wassermann reactions and pleocytosis in the majority of cases. Indeed, a parietic curve in association with positive blood and spinal fluid Wassermann reactions may be the earliest indications of impending dementia paralytica when the signs and symptoms of the disease are indefinite and uncertain.

STERILITY WITH ENDOCRINE DEFICIENCIES

To the Editor—A woman, aged 29 married six years apparently enjoys good health except for the following complaints. She is unable to become pregnant. The periods are irregular. Sometimes she misses one completely, they are of normal amount and duration. The patient's hair will not take a permanent wave (she tried four times in two years) since an operation for appendicitis about two years ago it was normal to that time. There is occasional arthritis of the middle fingers with no evidence of focal infection except sinusitis at times. The patient is 5 feet 5 inches (165 cm) tall and weighs 130 pounds (59 kg). Her habits are normal. The basal metabolic rate was plus 2 about eighteen months ago. Four tubal insufflation tests have been made in the past two years. The first test required higher than normal pressure but the others were fairly normal. At the time of the appendectomy a laparotomy was done and the pelvic organs were found to be normal. The tubes were traversed with a small probe and iodized oil was injected into the fimbriated ends. The external genitalia are normal. Alkaline douches have been taken before intercourse. The husband's spermatozoa have been found to be virile. What part do you think the pituitary and the ovaries have to do with these complaints? Please omit name.

M D Illinois.

ANSWER—A thorough and systematic investigation of both partners is indicated to determine the cause or causes of the apparent sterility. The history indicates several faults in the wife. A check-up of the husband may likewise reveal constitutional or endocrine causes for his share in the reproductive failure in spite of the finding of live spermatozoa.

In the wife a definite endocrine fault is suggested by the history of irregular menstruation, infertility, and the stringy condition of the hair. The latter probably relates to a thyroid gland deficiency, although the pituitary gland may be partly responsible. Lowered constitutional states may also cause changes in the texture and quality of the hair. The history of digital arthritis suggests a possible focus of infection and the recurrent sinusitis may well be responsible for this condition. The same condition may adversely influence the general constitution and thus predispose to lowered fertility. The disturbed ovarian function is probably only secondary to the other endocrine gland derangements. The therapy indicated is: 1. Attention to the sinus and any other foci of infection that may be discovered. 2. Endocrine treatment, thyroid extract may be given in small doses even if the metabolism measures within the normal range. The condition of the hair will probably improve on thyroid therapy and the menstrual cycle may become regular. 3. General hygienic and tonic measures.

If the health level in both partners is raised and their constitutional states are improved, fertility in their mating may be established.

APPEARANCE OF HEART MURMUR AFTER INJECTION OF DIPHTHERIA TOXOID

To the Editor—A boy aged 9 months was given one hypodermic injection of diphtheria toxoid (Lederle). Two able men had given him routine physical examinations previously and he was examined at the time of the injection and nothing abnormal was found. Six months later at another routine examination he is found to have an apparent cardiac enlargement with a loud rough mitral murmur. His mother states that neither previous to the injection nor since it has he had any type of infection especially any infection of the upper respiratory tract. Has not missed a meal and has not had any other symptom. Do you believe the toxoid is responsible here if not what else could be? Please omit name.

M D Connecticut

ANSWER—There is no evidence anywhere that diphtheria toxoid can produce a cardiac enlargement or murmur. Without any history of infection or any sign of illness from the time of the toxoid inoculation to the accidental finding of the cardiac signs, it can only be concluded that the condition had been present earlier. Cardiac murmurs are so common in infancy that the examiner frequently ignores them in the record even when he notices the sign on examination.

RECURRING HEMOLYTIC CRISES

To the Editor—An American girl aged 10 years has intermittent attacks of anemia occurring about every five or six months. She complains of "hurling all over" and marked weakness. Examination reveals a marked dyspnea, tachycardia and yellow skin. The hemoglobin (Tallqvist) is 16 per cent. The edge of the spleen extends almost to the crest of the ilium. The edge of the liver is at the umbilicus. The liver is tender. There is a hemic murmur in the heart. The coagulation time is normal. The red count is 250,000. The bleeding time is prolonged. The white count is 7,000 with 19 per cent small lymphocytes, 19 per cent large lymphocytes and 62 per cent polymorphonuclears. There is only a moderate anisocytosis but the shape of the red cells includes tennis rackets. The history revealed that liver extract by mouth had revived the patient from these attacks for several years. I gave it intramuscularly and the child gradually showed improvement. After three or four days of improvement hemorrhage began from the nose. This is the only place she has ever bled. The bleeding from the nose continued for two days and two nights regardless of treatment (the father's blood was used intramuscularly and fibrinogen was administered). No platelet count has been made. Repeated stool examinations show no ova. No infection or allergic evidence is found. Between these attacks the patient has a red count of about 1,000,000, the color index is from 0.9 to 1.1 and she is up and out with the children. My impression is that the child has an idiopathic thrombocytopenic purpura haemorrhagica. Please give me your opinion of this case. What do you think of splenectomy? What is the chance of cure with and without splenectomy? How high should the red count and hemoglobin be before the operation is performed? Please furnish other suggestions as regards treatment and operation.

JOHN D CAMPBELL, M D Duncan, Okla

ANSWER—It is possible that this patient has severe, recurring, hemolytic crises. This suspicion leads to a request for an estimation of the percentage of reticulated erythrocytes and of the fragility of the erythrocytes. If the percentage of reticulated erythrocytes is abnormally high and the fragility of the erythrocytes is increased, hemolytic icterus would almost certainly be the correct diagnosis and, in the event of exclusion of other diagnoses, splenectomy would be indicated. The question of thrombocytopenic purpura is raised in the query. The physician's notes do not indicate that clinically the features of hemorrhagic purpura have been consistently present, and there is no note concerning retractility of clot or platelet count. It is not indicated in the notes whether or not syphilis has been excluded. It would also be well to have roentgenograms of the skull and of the long bones, particularly to exclude the possible existence of Gaucher's disease or some other type of lipid histiocytosis. The erythrocyte count of 250,000 during attacks and a count of 1,000,000 when the child is up and about with other children are most likely clerical errors, if the count of 250,000 is correct it is one of the lowest on record. The question of treatment would depend entirely on accurate diagnosis. In the event of splenectomy it is desirable to have the erythrocyte count more than 3,000,000 before the operation, and splenectomy should not be done during an acute crisis.

VACCINATION OF ASTHMATIC PATIENTS

To the Editor—Will you please tell me what, if any, variation of reaction one gets in vaccinating asthmatic patients against smallpox? An instance came to my attention of a very severe reaction in a person who had asthma. Is it liable to produce more severe local reaction or set up asthmatic attacks? Kindly omit name.

M D Michigan

ANSWER—The reactions that may occur with smallpox vaccination in persons with asthma are similar to those that may occur with any foreign protein inoculation in any allergic individual. There is a tendency for nonspecific proteins to cause a more marked local reaction in allergic individuals. This is by no means constant nor does it occur in the majority. There is a similar tendency to produce a more severe systemic disturbance in allergic persons—a higher temperature and more marked malaise. This is probably due to the fact that the temperature-regulating mechanism in allergic persons is as a whole more easily disturbed. Frequently one sees for example, high temperatures with a slight rhinitis, constipation or other minor disturbances in asthmatic children.

It may be possible to precipitate an attack of asthma by non-specific means acting as a disturbing factor in overthrowing the allergic equilibrium. The reaction from smallpox vaccination may be such a factor. However, this is not very likely to occur. The more likely possibility is that the fever resulting from the vaccination may cause an actual temporary relief of the asthma when the latter is chronic. The latter effect of fever with or without infection, on the course of asthma and other allergic conditions is a frequent clinical observation.

It is possible that the patient may be sensitive to the beef protein contained in the vaccine virus. It is not likely, however, that there would be sufficient absorption from scratches to produce an allergic reaction. Such a response, if it should occur, would take place within a few minutes or an hour or two.

ENURESIS AFTER SPINAL INJURY

To the Editor—I have a patient aged 20 who in an accident received a crushing fracture of the third lumbar vertebra with involvement of the lateral arches also a fracture of the transverse processes of the fourth lumbar vertebra. There was no gross injury of the spinal cord. The reflexes are normal. Sensory reactions as well as muscle reactions and use of the limbs is normal. There is no residual urine. There is no difficulty with micturition during the daytime. There is no bladder infection. Blood tests are negative. Following the injury there was no difficulty in any way with injury or with the bladder and urine but there has now developed bed wetting. The patient had never had any such previous trouble since childhood. The sympathetic fibers that run through the sympathetic chain go through the third fourth and fifth lumbar roots. Could the fibers that go to the bladder have been injured at the time of the injury or could they be involved in callus formation at the present time? Stimulation of these sympathetic fibers causes increase of tone of the bladder sphincter. Could there be a degenerative involvement of these fibers with loss of tone of bladder sphincter resulting in bed wetting? If not just what would anatomically be the basis for this symptom, which is most distressing to the patient? Please omit name and locality.

M D Missouri

ANSWER—The sympathetic fibers innervating the bladder in man arise somewhere between the ninth dorsal and the fourth lumbar vertebrae. The exact origin is not known. They are motor to the ureterovesicular orifices, the trigonal musculature and the internal sphincter, and inhibitory to the detrusor muscles of the bladder. It is not likely that these fibers were injured at the time of the accident, since the difficulty with the function of the bladder came on much later, but they may be now involved in the formation of the callus.

The bed wetting from which the patient suffers is probably due to weakening of the internal sphincter. It is quite possible that there may be connective tissue adhesions which involve the nerves within the spinal canal. One might get some evidence by means of Queckenstedt's test or by injection of iodized oil into the spinal canal.

SALT IN HYPERTENSION AND IN PREGNANCY

To the Editor—In answer to a query by a physician in Iowa on pregnancy and hypertension published on page 1011 of the Sept. 29, 1934 issue of THE JOURNAL among other things it is stated that it is advisable to eliminate all salt from the food. The patient described by the physician who asks the question has a systolic blood pressure varying between 160 to 176 mm and has no edema. I should like to know why the man who wrote the answer proscribed salt. My recollection is that the work of the Fishbergs as well as that of others has definitely proved that sodium chloride plays no part in hypertension.

ALBERT W. HOLMAN, M.D., Portland, Ore.

ANSWER—The experimental results obtained by V. J. Harding and H. B. Van Wyck (*J. Obst. & Gynec. Brit. Emp.* 33:17, 1926) led them to conclude that "in the treatment of pre-eclampsia there is only one pertinent dietetic factor. It is the presence or absence of salt." Later (*Canad. M. A. J.* 24:635 [May] 1931) the same authors expressed the opinion that a high intake of salt, taken at the right moment, in a developing toxemia will produce an albuminuria, an increased blood pressure and convulsions in a short time. They therefore consider salt restriction a necessary part of prenatal care.

It is true that in recent years a great deal of doubt has been cast on salt as a harmful substance in cases of hypertension and the toxemias of pregnancy. In spite of this there are still adherents of a strictly salt-free diet in cases of hypertension (Allen, F. M., and Sherrill, J. N. *J. Metab. Research* 2:429, 1922 and Blaisdell, E. A. *Boston M. & S. J.* 196:808 [May 19] 1927). Most authorities agree that an excess of salt may be injurious. Probably the safest procedure is to permit patients who have hypertension to eat food that contains the customary amount of salt added during cooking. However, the patient should not add more salt when the food is eaten.

GLASSITE AS INDUSTRIAL HAZARD

To the Editor—I should like to know the composition of the abrasive Glasstite which is used in glass polishing and whether its use constitutes a hazard of silicosis. Please omit name.

M D Ohio

ANSWER—In Thomas's Register of American Manufacturers, in the section headed 'Leading Trade Marks' is the following entry: "Glasstite Bone Dry Black Rouge, James H. Rhodes & Co., 153 W. Austin Ave. Chicago, Ill. Black rouge is ferrosulfuric oxide (black iron oxide) having the formula $Fe_3O_4 \cdot H_2O$. This substance is widely used in glass polishing but is less used than the common red oxide of iron. The black oxide is less abrasive than the red oxide and is employed for scratch polishing and wherever a very fine finish is required. Black rouge is not an industrial toxic agent. Gross exposure causes practically no changes in the lungs. Very certainly it may not be classed as similar to silica in its action.

Any dusty lung disease produced should be termed 'siderosis' but so called cases of siderosis are often properly attributable to silica or silicates associated with iron ores. At this time the belief is that black rouge may not become the source of any direct pulmonary condition other than a minor 'increased noncharacteristic fibrosis'."

RENAL TUBERCULOSIS

To the Editor—A woman aged 26, a college graduate and athletically inclined married one year has been complaining of dysuria for the past two years. Cystoscopy has been done repeatedly by prominent urologists and she has been placed on various urinary antiseptics to no avail. Oil of Santal interferes with her digestion within twenty-four hours. The attacks last from several days to several weeks with relief for only three or four days at a time. On cystoscopy three months ago I found a moderately inflamed trigon and urethra. The left ureter was readily catheterized. A No. 6 catheter encountered an obstruction in the right ureter about 5 cm above the orifice but passed with some slight difficulty. Kidney function on both sides was normal. The urine from the right kidney pelvis showed several pus cells. The following week cystoscopy was repeated by a urologist in another city who had been treating her previously. He was able to pass a No. 9 catheter apparently with relative ease. She then had relief for more than a month. This physician has suggested pregnancy on the supposition that the resultant pelvic congestion may cure the condition. Roentgenograms show a spasmodic structure of moderate degree at the region of the obstruction. Physical examination is essentially negative. She has never had any inflammatory process in the abdomen or the pelvis. The patient is very desirous of having a child. Would you advise the risk of pregnancy? Is it true that pregnancy occasionally affords relief in such a condition? Have you any suggestions to offer other than repeated ureteral dilations? Incidentally bladder irrigations with silver nitrate potassium permanganate and mild silver protein have been tried with relief only during the time during which she was receiving treatment. Please omit name.

M D, New York.

ANSWER—The presence of pus cells in one kidney in a woman of 26 who complains of dysuria leads one to suspect that she might have tuberculosis of the kidney. Therefore it is in order to make repeated examinations of catheterized bladder specimens for the presence of tubercle bacilli. If they cannot be demonstrated in smear it might be well to inoculate several guinea-pigs. If pyelograms have been made, they should be studied carefully for the possibility of renal tuberculosis. It might be a good plan to have some plain roentgenograms made to rule out stone.

If dilation has been done with No. 9 bougies or catheters and if the trouble is due to a ureteral stricture, this amount of dilation should relieve the symptoms. Therefore I would discontinue further ureteral dilation and bladder treatments.

It may be possible that the symptoms are due to a chronic urethritis, and it may be a good plan to strip out the urethra for the presence of pus and to search for the presence of infection in Skene's glands.

Pregnancy probably would not relieve the patient of her symptoms. If the patient does not have renal tuberculosis, there would seem to be no reason why she should not become pregnant.

DIFFERENTIAL DIAGNOSIS IN ERYTHEMA MULTIFORME

To the Editor—A man aged 60 of Italian ancestry noticed a small bluish spot on the dorsum of the proximal phalanx of the left little finger. This gradually spread until it advanced across the back of the hand and up the arm. The skin seems to separate leaving a granulated surface dotted with islands of unharmed skin. Healing takes place without scarring. He reports to me that he has had five previous attacks at intervals of about two years. His physical examination and blood chemistry are negative. What is the diagnosis and what would you suggest in the way of treatment? Please omit name.

ANSWER—The periodicity of the attacks and the apparently extensive destruction of the skin which, however, proves to be too superficial a process to cause scarring, suggests erythema multiforme, which causes just such apparently gangrenous conditions. They are so superficial, however, that scarring never results. Erythema multiforme is typically bilateral and symmetrical. It is supposed by some to be caused by showers of bacilli producing emboli in the small vessels of the skin. It is conceivable that such a process might be active in the arteries of one arm. The vascular supply should be studied carefully. If possible, the patient should be seen by a dermatologist during an attack.

Erythema multiforme like eruptions are sometimes caused by drugs, quinine, iodine, bromine and some of the coal tar derivatives.

Recurrent erysipelas might be considered, but no bluish spot or deep erosions are apt to be seen in this disease. No diagnosis can be made without a careful study of the case which is evidently a rare one.

Arizona October Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held in Phoenix Oct. 2-3, 1934. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Four physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad	Per Cent
George Washington University School of Medicine	(1933)	85	8
Northwestern University Medical School	(1934)	85	2
School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
School of Medicine of the Division of the Biological Sciences University of Chicago	(1932)	Illinois	
St. Louis University School of Medicine	(1926)	Utah	
University of Tennessee College of Medicine	(1915)	Oklahoma	
Baylor University College of Medicine	(1931)	Texas	

Rhode Island October Examination

Dr. Lester A. Round, director, Rhode Island Public Health Commission, reports the written examination held in Providence, Oct. 4-5, 1934. The examination covered 7 subjects and included 70 questions. An average of 80 per cent was required to pass. Twelve candidates were examined, 10 of whom passed and 2 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine	(1934)	84*	89*
Boston University School of Medicine	(1932)	82	1
Tufts College Medical School	(1933)	84	5

Illinois October Examination

Mr. Eugene R. Schwartz, superintendent of registration, Illinois Department of Registration and Education, reports the written and oral examination held in Chicago, Oct. 16-18, 1934. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Sixty-five candidates were examined, 62 of whom passed and 3 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Chicago Medical School	78* 78 81 86	(1934)	77*
Loyola University School of Medicine	82 86*	(1934)	77

Book Notices

Accepted Dental Remedies Containing a List of Official Drugs Selected to Promote a Rational Dental Materia Medica and Descriptions of Acceptable Nonofficial Articles 1934 Council on Dental Therapeutics Cloth Price \$1 Pp 204 Chicago American Dental Association 1934

This book should be as valuable to the dental profession as are its prototypes, *Useful Drugs and New and Nonofficial Remedies*, to the medical profession. In format and general scope it resembles the former publication, but in that it lists and describes nonofficial remedies proposed for use by dentists it resembles the latter. The typography is excellent.

The names appearing in the list of members of the Council on Dental Therapeutics as well as the text of the rules governing the admission of articles assure both the scientific background and the practical soundness of the council's actions and consequently of the contents of this book. The official preparations included represent such an admirably short and selective *materia medica* as will be of most usefulness to the busy dental practitioner. The point of view of the dentist has been constantly and effectively kept in mind. It is planned to revise the list of drugs annually.

In a book such as this, sponsored by the dental association, both the professional and the lay reader will be much interested in the section devoted to dentifrices. The well informed will highly approve the sound and sane presentation of the subject. The council holds that "the sole function of a dentifrice is to aid in keeping the teeth clean by the removal of loose food debris by the mechanical use of the tooth brush." This offers small encouragement to manufacturers who would "protect the danger line," "avoid pink tooth brush" or propagate the many other fantastic claims advanced to make a "tooth conscious" public justify their advertising appropriations. The book lists some sixteen accepted preparations of this class, giving the composition and permitted claims for each. Among these appear the names of only two widely advertised products, 'Iodent Tooth Paste No. I' and 'Iodent Tooth Paste No. II.' With the descriptions of these appears a statement by the firm to the effect that no therapeutic claims will be made until sound evidence is available to warrant them.

The book contains descriptions of various accepted cod liver oils and related preparations. In the general discussion under which these are listed, the council takes a wisely conservative stand on the dental claims that may be made for such products. This is shown by the following statement:

Cod liver oil is considered to be among the medicinal foods which because of their vitamin content, apparently have a beneficial effect on the development of teeth and aid in the prophylaxis against dental caries. The exact role that vitamin D plays in such prophylaxis is at present not clearly understood (Diet and the Teeth Reports of the Council J. A. D. A. 19 1843 [Oct.] 1932)

The dosages given are based on the curative properties against experimental rickets in the absence of the available data no dosage is given for prophylaxis against caries or other dental diseases.

The bibliographic indexes at the end of the book give an idea of the scope and volume of the work done by the council on accepted products and subjects of general interest to dentists since 1930. Some ninety regular reports of the council and some twenty-five special reports, including those of the American Dental Association Bureau of Chemistry, have been published in the *Journal of the American Dental Association*. The bureau's report on mouth washes shows agreement between the Council on Dental Therapeutics and the Council on Pharmacy and Chemistry in skepticism concerning the much vaunted efficacy of these preparations.

The book has a well prepared section on symptoms and treatment of acute poisoning, a list of recorded solubilities, helpful tables of weights and measures and a therapeutic index based on that given in the latest edition of Cushman's *Pharmacology and Therapeutics*. There is an adequate index to the text of the book itself.

The American Dental Association is to be congratulated on this new step in the fostering of rational therapeutics, for which it is indebted to its excellent Council on Dental Therapeutics. It is to be hoped that the book will receive from dental practitioners the attention—and support—it so well deserves.

Krebs und Vererbung. Von Prof. Dr. Hans R. Schlinz und Dr. Franz Buschke. Paper. Price 21 marks. Pp. 280 with 160 illustrations. Leipzig: Georg Thieme 1935.

This is a critical review of much of the present-day literature on the influence of heredity on the occurrence of cancer both in man and in experimental animals. After a brief presentation of the principles of heredity in the light of modern work, the literature on the genetics of spontaneous tumors in laboratory animals is reviewed. From the evidence now available the authors conclude that "at present the assumption of a simple recessive factor for the adenocarcinoma of the mamma of the mouse is most easily harmonized with the observed facts which conclusion is in agreement with the views advanced in this country by Maud Slye. They further state, however, 'But we must be clear that this conclusion is valid only for this one tumor' and cannot be applied indiscriminately to all tumors. They then consider some of the evidence on the genetics of human tumors, of transplanted tumors in animals and of the tumors produced by chemical or parasitic stimulation of tissues. As to the relative importance of hereditary and environmental influences in the production, the evidence indicates that this varies greatly with different sorts of tumors thus there are three great groups: 1. Cancers almost entirely dependent on the hereditary background, e. g., retinal gliomas; 2. Cancers in which the exciting stimulus is much more important than the heredity, as with superficial cancers resulting from protracted stimulation by tar, x-rays, and so on, but even here the hereditary background is a primary factor in determining at least the time required to produce such cancers; 3. The majority of human cancers, which seem to lie between these two groups, the hereditary background being essential and the exciting agent often being a physiologic stimulus (e. g., the influence of endocrine stimulation of mammary gland cancers). Apparently, with glandular cancers the heredity factor seems to be more important than with squamous cell carcinomas. While active workers in the field of cancer etiology and genetics will probably take exception to many statements and deductions made by these authors as they do with one another's utterances in this new and unstabilized field, this publication gives a good general survey of an important subject—perhaps the best now available. An extensive bibliography is appended.

Clinical Pathology of the Jaws with a Histologic and Roentgen Study of Practical Cases. By Kurt H. Thoma, D.M.D., Charles A. Brackett, Professor of Oral Pathology in Harvard University. Cloth. Price \$9. Pp. 643 with 423 illustrations. Springfield, Illinois and Baltimore: Charles C. Thomas, 1934.

This book contains a wealth of material that is not available anywhere else. The author has had an unusual opportunity to study lesions of the jaw bones from the point of view of the clinic and the laboratory and has been diligent and faithful in the accumulation of the records of this experience, such as case histories, photographs and histologic slides. Of the illustrations, 189 are reproductions of roentgenograms, more than 100 are prints of photomicrographs of histologic preparations and the remainder are photographs and drawings chiefly of the gross aspects of jaw disease. There are 171 case histories, of which eighty-three concern tumors, twenty-three deal with cysts and the remainder have to do with all other conditions. Each of the chapters has a generous bibliography, especially those on malformations, endocrine disturbances and tumors. There are two indexes, one of the conventional type, which is quite adequate, and one for the case histories. Because of the general excellence of the book, minor defects become unduly conspicuous. Most of the illustrations are without legends, so that one has to refer to the text for names and explanations; the task of coordinating reading and study of the illustrations is thereby made unduly laborious. All of the illustrations except many of the photomicrographs attain a high standard of excellence, partly because of technical superiority in reproduction and the high quality of the paper used. Since the interpretation of even an excellent histologic illustration is generally difficult for the average reader there is little excuse for the use of inferior reproductions of tissue sections. The statement on page 140 that 75 per cent of the infections of the maxillary sinus are secondary to infections of the teeth should be questioned as it seems too high. The failure to refer to Gilmer's work on jaw fractures and to Partsch's con-

tribution to the treatment of jaw cysts should be noted. For a first edition there are relatively few minor errors in printing and proofreading. This text is highly recommended to all those interested in diseases of the jaws, including medical and dental students, teachers and clinicians.

Über Carcinome Sarcome und Lymphomatosis Infiltrans bei weissen Mäusen. Versuche menschlichen Cancer auf Versuchstiere zu übertragen. Von Johs. V. Andersen. Mit einer englischen und dänischen Zusammenfassung. Paper. Pp 143 with illustrations. Copenhagen. Levin & Munksgaard 1934.

For many years, investigators of cancer have endeavored to transfer neoplasms from one species to another by grafting. Recently the German investigators Keysser and Heidenhain stated that they were able to transfer human cancer to mice. While of no practical interest, except in arousing fears of the layman that he may catch cancer from laboratory animals, these statements have considerable biologic importance. Andersen has repeated all this work on a large scale and has found that it is almost certain that the tumors which Keysser and Heidenhain observed in their mice were spontaneous mouse tumors and not transplanted neoplasms derived from the human tumors which they had inoculated into their animals. The care with which Andersen's work is done, the accurate statistical analysis of the experimental material and the admirable photomicrographic reproductions of the tumors found will render unnecessary any future repetition of such experiments.

Questions cliniques d'actualité. 4^e série. Par MM. Armand Delille et autres. Leçons professées à charité aérologie du Professeur Sergoni. Paper. Price 45 francs. Pp 280 with 33 illustrations. Paris. Masson & Cie 1934.

The fourth volume of clinical discussions presented at the Hôpital de la Charité, Paris, France, covers the discussion of a variety of clinical and related problems by eminent French clinicians. The character and scope of these lectures varies from the empirical to the philosophical, as is illustrated by the following titles: the principal forms of onset and diagnosis of pulmonary tuberculosis in the child; pneumothorax in various clinical types of pulmonary tuberculosis; the pseudolithiasis form of carcinoma of the ampulla of Vater; a new technique for the treatment of lung abscess; dissociated symptoms of hypothyroidism in the child; the treatment of arterial obstruction in the extremities; acute primary infectious purpura; the mean arterial pressure and its importance; the danger of simple explanations in biology and medicine; a case of malignant granulomatosis with a mediastinal syndrome; periarteritis nodosum; clinical and anatomic studies of disseminated sclerosis; the general and therapeutic principles of bacteriophage; hyperpyrexia in nurslings; diaphragmatic hernia; some clinical considerations of the phrenic nerve; spirochetal meningitis; the onset of acquired characteristics. The character of the subjects presented by such representative authors offers a good index of French thought in clinical medicine and should therefore interest the general reader in medicine. This volume, however, is of little value as a general reference work on the various subjects discussed because of the lack of references to the international literature and the point of view, which is limited to the French school.

Recent Advances in Ophthalmology. By Sir Stewart Duke Elder, M.A., D.Sc., Ph.D., Ophthalmic Surgeon and Lecturer in Ophthalmology, St. George's Hospital, London. Third edition. Cloth. Price \$4. Pp 434 with 153 illustrations. Philadelphia. P. Blakiston's Son & Company 1934.

In the present edition the author follows the general outline of the previous work but omits the first four chapters of the second edition on the nature of light, physiologic optics, embryology and methods of diagnosis. He has divided his previous chapter on physiology into separate and more comprehensive ones on vascular circulation, intra-ocular fluids, intra-ocular pressure, the vitreous body and the effect of drugs on the eye, bringing these subjects down to date. The last mentioned chapter is an excellent review of the action of the drugs commonly used in study and therapy in ophthalmology. The second edition was chiefly concerned with glaucoma, cataract and neurology. In this edition the latter is omitted and the first two subjects are enlarged on. In the second part, on diseases of the eye, the author reviews intra-ocular infections, ocular pigment and intra-ocular tumors, disease of the conjunctiva,

cornea and retina, and sympathetic ophthalmia. In discussing sympathetic ophthalmitis he mentions but takes little stock in Meller's contention that the disease is due to the tubercle bacillus. The chapter on retinal detachment is especially good in that it reviews the best work on this subject, gives the technique of the various operations accompanied by the author's own illustrations, and compares the results of the various methods. The discussion of cataract has been enlarged to contain newer knowledge of the metabolism and chemistry of the lens, as well as the electrodiaphane method for extraction introduced by Lacarrere. He also gives Sinclair's tables showing the visual results and complications in a series of 257 intracapsular extractions. The book is well written and illustrated; is a handy reference volume, and may be highly recommended for the student and practitioner.

A Text Book of Pharmacology and Therapeutics or the Action of Drugs in Health and Disease. By Arthur R. Cushny. Tenth edition revised by C. W. Edmunds, A.B., M.D., Professor of Materia Medica and Therapeutics in the University of Michigan, Ann Arbor, Mich., and J. A. Gunn, M.A., M.D., D.Sc., Professor of Pharmacology in the University of Oxford, Oxford, England. Cloth. Price \$6.50. Pp 786 with 75 illustrations. Philadelphia. Lea & Febiger 1934.

This textbook has again been revised by the same pharmacologists who made the first revision following Dr. Cushny's death. They pay tribute to the original author with a biographic sketch, which replaces his preface to the eighth edition. The present edition brings the text into accord with the British Pharmacopoeia of 1932, just as the ninth edition complied with the Pharmacopoeia of the United States, tenth revision. This procedure results in the text being of use to both English and American students. There is a new section dealing with the liver and stomach preparations used in the treatment of primary anemias. The section on vitamins is elaborated. Carotene is included in the discussion of vitamin A and the division of vitamin B into B₁ and B₂ (G). There is additional material on iron and its compounds, more especially as to its administration. The section on bismuth is extended to include further material on its use in syphilis. There is a new section under hypnotics, which deals with the older and the newer barbiturates. The subject of digitals has been revised in the light of the latest developments in its chemistry. The paragraphs on therapeutic uses immediately follow those on pharmacologic action instead of the lists of preparations being interposed as in the previous editions. There are over forty additional pages and two additional illustrations. The book is an excellent, modern textbook and reference work on the subject of pharmacology and therapeutics.

Opuscula selecta Neerlandicarum de arte medica. Fasciculus duodecimus quem cutores miscellaneorum quae vocantur Nederlandsch Tijdschrift voor Geneeskunde collegerunt et ediderunt. Amstelodami Sumptibus Societatis. Vorli auctores de symphysiotomia. Cloth. Pp 383 with illustrations. Amsterdam 1934.

This volume reprints in Dutch thirteen articles by Dutch physicians on symphysiotomy, published originally between 1771 and 1831. There is an introduction of thirty-two pages, and occasional comments appear by Dr. F. M. G. de Feyfer, who has made a special study of symphysiotomy in Holland up to 1840. Some of the articles are illustrated and there are five portraits. The book will be of great interest to students of the history of obstetrics.

The Hospital Yearbook. A Reference Book on Planning Equipment Administration and Purchasing. Thirteenth edition. Cloth. Price \$2.50. Pp 543. Chicago. The Modern Hospital Publishing Company, Inc. 1934.

The planning and administration of a modern hospital involve more details than any one man can master alone; be he physician, architect, trustee or superintendent. The Hospital Yearbook presents a collection of information representing the contributions of a score or more of experienced hospital executives, architects and consultants. The first 200 pages consist mainly of concentrated check lists covering every conceivable detail in planning for ward patients and private patients, surgical facilities for the general hospital, the outpatient department, the maternity, children's, tuberculosis and psychopathic departments for the general hospital, contagious wards for the general hospital, laboratories, x-ray department, physical therapy facilities, hospital laundries, hospital kitchens, and the nurses' home. It is not assumed that any hospital

would include in its plans everything that is suggested. These lists are indispensable in the selection of proper equipment, devices, supplies, materials and layout. Following the planning section are articles on small hospitals, engineering, economics, contracting, modernizing, cost analysis, fire protection, air conditioning, equipment purchasing and supply lists. The administration section presents model articles of incorporation and by-laws, check lists for trustees, duties of the superintendent, major department heads and repair department. These are followed by condensed articles by qualified writers on noise, accidents, publicity, collections, accounting, costs, depreciation, insurance and numerous similar topics of everyday concern to the superintendent. The book is regarded as a valuable supplement to any textbook on hospital management and is a commendable start toward a compendium of standard reliable hospital information.

Endogene Faktoren in der Tumorgenese und der heutige Stand der Versuche einer biologischen Therapie. Von Professor Dr. G. Fichera, direttore generale dell'Istituto nazionale Vittorio Emanuele III per lo studio e la cura del cancro. Milano. Autorisierte Übersetzung aus dem italienischen Paper. Price 7.50 marks. Pp. 83 with 105 illustrations. Berlin: Julius Springer 1934.

The basis of this monograph is the possibility that extracts of certain organs particularly the spleen, lymph nodes and marrow, may be of benefit in the treatment of malignant tumors. The author believes that the clinical trial of such extracts is desirable. The experimental and other data on which the method is founded are presented.

Medicolegal

Workmen's Compensation Acts Alleged Refusal of Employee to Submit to Medical Treatment.—In the course of his employment, on December 23, Hail ran a file in his hand. A clerk of the employer, who had charge of the employer's first aid station, washed the wound, applied certain preparations, and rendered "medical attention" to the employee daily for the succeeding three days. Until January 2, the workman's wife bathed his hand every evening in hot water in which she put some sort of antiseptic. The hand seemed to be improving and, according to lay testimony, was healed from the outside. On January 2, however, there was a swelling and the workman went to a physician. On January 4, a fever developed and he was taken to a hospital, where he died January 7 from septicemia. His widow was awarded compensation by the workmen's compensation commission. The employer then appealed to the St. Louis circuit court, contending that the workman had unreasonably refused medical treatment. To sustain that contention, he relied on the testimony of the clerk in charge of the plant's first aid station and of the plant foreman that they had suggested to the workman on several occasions that he go to a physician, but that on the workman's assuring them that he did not believe the injury was serious enough to warrant that they refrained from insisting that he do so and at no time named any particular physician for him to see. Two medical witnesses, one called by the plaintiff and the other by the defendant, testified, in effect, that even if the workman had been treated by a physician from the inception of his injury, septicemia might still have developed. The court affirmed the award of the commission and the defendant appealed to the St. Louis court of appeals.

It cannot be said as a matter of law, said the court, that under the facts of this case the workman unreasonably refused to submit to medical treatment. It does not conclusively appear that he refused at all. While the defendant's witnesses testified that the workman refused to go to a physician, though repeatedly told to do so, they further testified that they merely suggested that he go to a physician or advised that he ought to do so. A mere negligent failure on the part of the workman to obtain or accept medical treatment, though advised or urged to do so, does not bar a recovery of compensation. To bar a recovery, an unreasonable refusal to submit to medical treatment must be shown and the burden of proving that refusal is on the employer. The court held that the commission was

warranted in holding that the employer had failed to offer the required proof. The award of compensation was accordingly affirmed.—*Hail v. Champion Shoe Machinery Co. (Mo.), 71 S. W. (2d) 146.*

Malpractice Negligent Treatment of Fracture.—The plaintiff sustained a simple comminuted fracture of the middle third of his right femur. The defendant-physician, apparently without attempting to reduce the fracture by nonoperative procedures, made a 10 inch incision on the right thigh and attempted to place the broken ends of the bone in juxtaposition. Thereafter infection developed and it became necessary to amputate the leg just below the hip. The plaintiff sued the defendant for malpractice and obtained judgment in the trial court, from which the defendant appealed to the Supreme Court of Appeals of West Virginia.

The plaintiff contended that it was the duty of the defendant to follow a method of treatment established and approved by physicians and surgeons generally in the same community, or similar communities, and that the defendant did not do so. In *Broxton v. Hoffman*, 86 W. Va. 468, 103 S. E. 484, it was held, said the court, that if there are two or more approved methods of treatment of an injury a surgeon may adopt the one which, in his honest opinion, will be more efficacious and appropriate under all the circumstances, and in such case he is not liable for any injury resulting from an error in his judgment, if there is one. He is not bound at his peril to adopt the best method. In the present case the experts generally agreed that the injury could have been properly treated by the "closed" or nonoperative method. The trial court instructed the jury that it was the duty of a physician to adopt in the treatment of a case the method established and approved by physicians and surgeons generally in the community in which he performs the operation or gives the treatment and that, if they believed from the evidence that the defendant did not adopt an approved and established method of treatment of a fractured leg such as the plaintiff was suffering from at the time the treatment was administered, or if they believed from the evidence that the defendant was negligent or careless in the application of the treatment of the injury and did not use the degree of care employed by physicians and surgeons generally in the treatment as was used in the community in which he performed the operation or treatment at the time thereof, then their verdict should be for the plaintiff. This instruction, said the Supreme Court, correctly stated the law.

The fact that it became necessary, continued the court, to amputate the patient's leg did not of itself establish negligence, but it was a circumstance which the jury had the right to take into consideration in determining whether the defendant was guilty of negligence. Furthermore, according to the evidence, a roentgenogram should have been taken immediately following the operation to ascertain whether the bone was in place and without angulation. This was not done. According to the plaintiff's testimony, the defendant had neglected him for as much as five days at one time and eight days at another, during all of which time the plaintiff was undergoing much agony. While the defendant denied such neglect, the plaintiff was corroborated by another patient located in close proximity to him, and by one of the nurses. After reviewing the entire record, the Supreme Court was of the opinion that the defendant received a fair and impartial trial and that the record disclosed no reversible error. The judgment of the trial court, therefore, was affirmed.—*Marxell v. Howell (W. Va.) 174 S. E. 553.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk () are abstracted below.

American Journal of Anatomy, Philadelphia

55: 343-528 (Nov. 15) 1934

- Some Features of Cleavage in Living Egg of the Rat. Elizabeth MacDonald and J. A. Long. San Francisco—p. 343.
Anterior Hypophysis of Rabbit During Estrus and Pseudopregnancy. J. M. Wolfe, Doris Phelps and R. Cleveland. Nashville, Tenn.—p. 363.
New Formation of Arteriovenous Anastomoses in Rabbit's Ear. E. R. Clark and Eleanor Linton Clark. Philadelphia—p. 407.
Cecus of Fossa of Allen and Associated Structures. A. W. Meyer. San Francisco—p. 469.
Incidence of Patent Foramen Ovale Cordis in Adult American Whites and American Negroes. G. A. Seib. St. Louis—p. 511.

American Journal of Public Health, New York

24: 1197-1284 (Dec.) 1934

- Previous History of Poliomyelitis in California. J. D. Dunshee and I. M. Stevens. San Francisco—p. 1197.
Poliomyelitis, 1934. J. L. Pomeroy and G. H. Roth. Los Angeles—p. 1201.
Epidemiology of Poliomyelitis in California, 1934. J. P. Leake, E. T. Cedar, W. P. Dearing and A. G. Gilliam. Washington, D. C., and H. D. Chope. San Francisco—p. 1204.
The 1934 Epidemic of Poliomyelitis in Los Angeles. Preliminary Report on Pathologic Changes in the Nervous System. R. Van Wart, C. Courville and E. M. Hall. Los Angeles—p. 1207.
Clinical Features of Poliomyelitis in Los Angeles. A. G. Bower, R. W. Meals, Mary Bigler, J. Ewing and V. Hauser. Los Angeles—p. 1210.
The 1934 Epidemic of Poliomyelitis in Southern California. G. M. Stevens. Los Angeles—p. 1213.

Silicosis. Study of One Hundred and Six Pottery Workers. P. A. Quaintance. Los Angeles—p. 1244.
Salmon Inspection. R. W. Clough and E. D. Clark. Seattle—p. 1252.

The Los Angeles Poliomyelitis Epidemic.—Kessel and his associates state that the mortality rate of the 1934 poliomyelitis epidemic in Los Angeles has been exceptionally low and the amount of residual paralysis less than usual. The proportion of adults infected has been higher than is common. An exceptionally high rate of communicability has been noted. This was especially apparent among hospital employees in the communicable disease unit of the Los Angeles County Hospital of whom 119 per cent developed poliomyelitis. Certain preliminary observations from the laboratory during this epidemic are as follows: Employees receiving convalescent pooled and normal pooled poliomyelitis serum as a prophylactic measure demonstrated no less degree of susceptibility than employees working under similar conditions who received no serum. There is slight evidence that those receiving prophylactic serum developed less severe symptoms than those who received no serum. Convalescent pooled serum was no more effective when given therapeutically than normal pooled serum. A small proportion of the patients reported serum reactions, ranging from a mild to a severe type of serum sickness. A high proportion of those who demonstrated positive serum symptoms responded to skin sensitivity tests with human serum. Spinal cell counts of poliomyelitis cases demonstrated that 27 per cent showed no white cells, 38 per cent from 1 to 9 cells and 35 per cent 10 or more cells. Of those showing more than 10 cells, 50 per

cent gave a positive colloidal benzoin reaction. Attempts to inoculate monkeys with virus from eleven necropsy cases have given positive results in five. The virus appears to possess an antigenic relationship to the M V strain, since monkeys that recovered from inoculation with the California strain are resistant to subsequent inoculation with the M V strain.

Danger of Sudden Deflation of Acutely Distended Intestine.—Elman made a few clinical and experimental observations which suggest that serious symptoms and death may be caused by sudden decrease of the high intra-intestinal pressure present in the distended intestine in certain late cases of low intestinal obstruction. That the unfavorable result is directly connected with the coincident release of the intra-intestinal pressure seems to be suggested from the evidence. The lethal outcome that may occur after surgical deflation of a tense obstructed intestine must be due either to the operation itself (anesthesia, surgical shock) or to some untoward result of the procedure employed during the operation. The idea of Wilkie's that death is a circulatory one due to extensive loss of blood and fluid into the paralyzed dilated splanchnic capillaries is not supported by the clinical symptoms of these patients or by their failure to respond even when large amounts of blood and fluid are given. If one assumes that the fall of intra-intestinal pressure may actually be the cause of death, it is easy to explain the train of events on a mechanical basis. In a distended obstructed intestine, circulatory changes in the wall begin soon and in a few days may become quite marked and in fact lead to localized patches of gangrene showing through and often involving the muscularis of the wall opposite the mesentery where the circulation is the poorest. Even in the absence of visible gangrene there is ample evidence of edema, swelling and foci of necrosis and even actual loss of the mucosa in fatal cases examined at necropsy. The normal intestinal mucosa is a rather efficient barrier against the entrance of the many poisonous fecal elements that swarm in abundance in perfectly normal contents of the lower intestine. This barrier depends on the selective action of living intestinal epithelium. When these epithelial cells become damaged this power must be impaired and poisons and bacteria may traverse the barrier from the intestinal lumen into the circulation. It is not the mere presence of damaged mucosa that is important. Post-operative toxemia is probably due to the fact that, while intra-intestinal pressure is high enough to interfere with the blood flow through the intestinal wall, an efficient barrier is still present between the fecal content and the circulation, provided, that is that the pressure is not great enough to force passage through the entire intestinal wall into the peritoneal cavity. According to this idea, then, the intestinal distention for a time at least acts as a protection against absorption of toxins or bacteria. Now, whenever the intra-intestinal pressure falls

sufficiently, the blood flow through the intestinal wall begins again and there is nothing now to prevent intestinal toxins and bacteria from entering the dilated capillaries. The failure to demonstrate toxins or bacteria in the blood of patients or animals sick or dying of low intestinal obstruction does not necessarily invalidate the theory. This conception fits in with the unpredictable behavior of these cases clinically and experimentally. The element of intra-intestinal pressure in preventing or promoting a toxemia in late low intestinal obstruction by its effect on the barriers is one that merits greater study and consideration.

Gastric Acidity in Carcinoma of Stomach—Comfort and Vanzant studied the records of 619 men and 186 women with carcinoma of the stomach, in whom the nature of the disease was confirmed at operation or by subsequent observation and the results of gastric analysis were available. In cases of carcinoma of the stomach, the incidence of achlorhydria was about three times the normal and the mean free acidity was lowered about 14 points in men and 8 in women. Curiously, carcinoma seems to injure the acid-secreting mechanism of men more than it injures that of women. The range of acidity for men with carcinoma of the stomach was found to be from 0 to 90 units, which is only 10 points short of the range for normal men. On comparing percentage distribution curves of acidity of normal persons and of patients with carcinoma of the stomach it was seen that the difference comes in the upper part of the range beyond the point marking 20 units. In the group of patients with carcinoma of the stomach who had free acid, the total acidity was but slightly lower than normal. In this group the combined free acidity was slightly above normal. In the achlorhydric group the total acidity was slightly above normal. The incidence of achlorhydria increased with age among persons with carcinoma of the stomach just as it does among normal persons. The only difference was that the actual percentages at the different ages were greater. Among men with carcinoma of the stomach there was the normal falling off in free acidity with age but the curve was different from that of normal men. Gastric acidity was not influenced markedly by the degree of anemia, loss of weight, situation of the growth or the volume of gastric contents. Marked differences in gastric acidity were noted when the cases of carcinoma of the stomach were divided into three groups, according as they had either an ulcer-like, a pseudo-ulcer or a nonulcer type of history. In the ulcer-like group the incidence of achlorhydria and the range of free acidity were practically normal and mean free acidity was only 5 or 10 units below normal. The two distribution curves were almost identical. In the nonulcer group the incidence of achlorhydria was about four times normal. The range of free acidity was shortened by about 40 units, and mean free acidity was lowered by 20 units in the case of men and by 10 units in the case of women. In the pseudo-ulcer group the distribution curve representing acidity lay between the other two curves but somewhat nearer that of the group in which the history was not that of ulcer. The data suggest that in the nonulcer group the carcinoma often develops in an anacid stomach, and that in the ulcer-like group the lesion begins in a normally acid stomach.

Method for Reduction of Vertebral Fracture Dislocations—Stookey presents a method for the reduction of incomplete fracture dislocations that may be employed immediately after the injury, can be maintained as long as may be desired, and is available in any hospital having an air mattress. Reduction of the dislocation is accomplished without manipulation and usually no special skill is required. With slight modifications the principle of the method may be used for transporting patients with acute spinal cord injuries by substituting a stretcher for the bed and using an air mattress. The technique used is as follows: A fracture board is placed on the springs in the usual manner. The foot end of the bed is placed on low blocks elevated slightly in order to raise the relative position of the patient's head to his trunk. In order to have the head easily accessible, the foot end of the bed is made the head of the bed. Two ordinary mattresses are placed over the fracture board. A blanket is then rolled and placed on the ordinary mattresses at the level of the shoulders for fracture dislocations of the cervical vertebrae or at whatever level may be indicated

for fractures of other regions of the spine. An air mattress preferably 8 inches thick, is then placed on the bed over the blanket roll and a strip of adhesive tape, 8 inches wide if the fracture is in the cervical region or from 12 to 14 inches wide if the fracture is in the thoracic or the lumbar region, is applied to the mattress beginning at the line of the blanket roll. The mattress is covered with a soft woolen blanket or a sheet and the patient is placed on the bed. The adhesive strip is then drawn as tight as possible, as much force being used as is necessary to obtain the proper degree of angulation of the air mattress. It is then fastened to the bottom of the foot piece of the bed either directly or to a movable bar attached to the foot end a ratchet being used to tighten as needed. The air mattress must not leak and must be kept pumped up, and the adhesive strip must be tight at all times. A pillow is then rolled and placed beneath the patient's knees so as to flex the lower extremities slightly. A small folded blanket is placed beneath the calf muscles, reaching to within 4 inches of the insertion of the achilles tendon. The heels are thus kept off the bed by resting the calves on a wide surface and pressure sores of the heels are thus avoided. Any abnormal position of this sort is naturally uncomfortable and the author has found it advisable to relieve the patient's discomfort during the first few days by medication. If each of the details is carefully observed he believes that the foregoing method will be found satisfactory for the reduction of incomplete vertebral fracture dislocations, especially in the cervical region, and for the reduction of compression fractures of the whole spine.

Origin and Nature of Pigmented Nevi—Becker states that the examination of several hundred pigmented nevi by modern histologic methods showed that they consisted of one or two types or a combination of the two. The first is the strictly cellular type, which results from the multiplication of the clear cells in the epidermis with or without penetration into the dermis, the second is the nerve type, which is deeper and the structures of which often simulate those of tactile corpuscles. The use of the term "schwannoma," as suggested by Masson, is not illogical, although more work must be done before the origin of clear cells and nevi in the sheath of Schwann can be proved. The terms nevus and nevoid are ambiguous and could be replaced by the term prenatal without losing any of their significance.

Lipoid Diabetic Necrobiosis—Zeisler and Caro report two cases of lipoid diabetic necrobiosis (Urbach-Oppenheim), with postmortem observations in one case. Lipoid diabetic necrobiosis is a rare disease of the lipoid and carbohydrate metabolism, characterized by yellow to buff-colored scleroderma-like plaques on the lower extremities. The histologic changes

are pathognomonic and consist primarily of vasculitis with perivascular lymphocytic infiltration and extensive necrobiotic areas in the corium containing swollen collagen fibers, which are infiltrated by droplets of lipoids of undetermined nature. The pathogenesis of the disease is explained by a deposition or imbibition in the necrobiotic intercellular connective tissue of the excess lipoids present in the blood, following changes in the cutaneous blood vessels caused by the diabetes. The lesions must be differentiated from xanthoma, amyloidosis, scleroderma and similar dermatoses. The disease is chronic and is resistant to treatment with insulin and to diets low in fat.

Hinton Test and Lumbar Puncture in Syphilis—Hinton made a study of 361 consecutive patients with primary and secondary syphilis to ascertain what effect the use of the Hinton blood test would have on the number of examinations of spinal fluid that are desirable as aids in determining the persistence of the infection within the first two years of the disease. In each case the diagnosis of syphilis was made on a combination of definite clinical and laboratory criteria. Seventy per cent of the cases of primary syphilis gave positive results in a dark field examination and all cases of secondary syphilis showed a positive reaction of the blood with a rash or other unmistakable signs of the secondary stage. Of the 361 patients, 153 were under observation and treatment for more than twelve months and had blood tests between the twelfth and eighteenth months. Of the remaining 208 patients, sixteen in the primary stage never had a positive reaction of the blood or later clinical signs of the disease. 182 patients were under observation or treatment for less than a year, and ten of those observed and treated for more than twelve months had no blood tests between the twelfth and eighteenth months. The observations of the 153 cases have pointed out that, with the aid of an unusually sensitive blood test for syphilis, lumbar punctures are not necessary during the first two years of the disease for the purpose of determining the persistence of the infection. That the infection may persist, in spite of even a negative reaction to the Hinton test has been indicated by serologic relapses in twelve cases. In none of six of these cases in which lumbar puncture was done did the examination of the spinal fluid help more than the Hinton test in determining this persistence.

Treatment for Common Warts—Sutherland-Campbell first used the following procedure on a patient who was given a maximum of roentgen and radium therapy for warts that involved the finger-tips of both hands, without effect. With a fine spark the verrucous surfaces were seared lightly. The patient returned at weekly intervals and the procedure was repeated. Involution and desquamation of the lesions occurred within six weeks. At this time the author attributed the reaction to (1) a result of the combined action of the treatment with rays of short wavelength and the superficial electrodesiccation or (2) spontaneous healing. Use of the procedure for twelve months has demonstrated to him that it is the method of choice and is the solution of what can be a vexing problem. The degree of pain experienced during treatment, except in rare instances, is negligible and tolerated easily. In only one case has it been necessary for the author to use procaine hydrochloride. The method is superior to surgical removal or electrodesiccation proper. The method may be termed superficial fractional desiccation. In employing it the surface of the wart is cleansed. A moderate spark is used commencing inside the margin of the corneus collaret, the border of the wart is circled, and then only the surface of the wart proper is seared and carbonized. The procedure is repeated at biweekly intervals. There have been no recurrences following five or six treatments, which is the number given ordinarily. Only one patient with plantar warts has been subjected to this form of therapy, with the usual good result.

Postencephalitic Trophic Ulcer—Greenbaum and Alpers believe their case to be the first reported instance in America of trophic ulceration of the skin occurring during the chronic stages of epidemic encephalitis. Although the condition is benign it is diagnostically important. It is generally believed that trophic ulcers are the result of two factors—trauma, usually

in the form of pressure, and degenerative changes in the sensory and nutrient fibrillae of the affected nerves. The latter factor is, of course, essential and occurs in connection with a number of diseases of the central and peripheral nervous system, but trauma (mechanical or infectious, or both) is of undoubted etiologic importance. All the ulcers reported in the German literature occurred in practically the same location—the nasolabial groove. Itching at the site of the ulcer was a usual premonitory and accompanying symptom. The first case was reported by Hoffmann in 1926. In the same year Lammernan reported a case, in 1929 Petzal reported the third, and in the same year Schlitter reported the fourth case.

Prenatal Medication as the Possible Etiology of Deafness—Taylor suggests that perhaps the reason why the otologist has practically ignored the subject of prenatal medication as a possible etiologic factor of deafness in the newborn is that a child must be $2\frac{1}{2}$ or 3 years old before a diagnosis of nerve deafness can be made. By that time the prenatal history has been dismissed. The history which the otologist usually endeavors to get consists principally of whether there has been a family history of deafness, consanguinity, hereditary syphilis or meningitis, and with these details the subject is generally closed. To some, however, the history of the drugs given the mother during pregnancy is of as much importance as whether the patient had a great-uncle or a second cousin who was deaf. If it were possible to ascertain the incidence of nerve deafness among the children registered in schools for the deaf in the United States and, by questioning the mothers, to gather information regarding their intake during pregnancy of drugs which may produce nerve deafness, the results might constitute a dramatic incident in the history of otology. The author states that certain drugs have a predilection for the auditory nerve. Idiosyncrasy for drugs may be an important factor in causing nerve deafness. Quinine takes precedence among the drugs causing nerve deafness and is frequently used during the term of pregnancy. Evidence has been presented that certain drugs which have a predilection for the auditory nerve readily pass through the placenta when administered to the pregnant mother and may be toxic to the fetus, a possibility which the otologist has virtually ignored. Prenatal medication as a possible etiologic factor of deafness in the new-born is of sufficient importance to warrant the cooperative research of the biochemist, the histopathologist, the obstetrician and the otologist.

Sinus Headache—Fox says that in acute sinusitis there are two general types of pain—the neuralgic and a constant type, more or less localized in the region of the diseased sinus. The neuralgic type of pain is invariably present during the morning and gradually disappears before early afternoon. This pain may be followed by a sensation of fulness and pressure in the sinus. The pain begins in the sinus but may be so severe as to involve adjacent nerves. The second type of pain in acute cases is constant discomfort in the region of the sinus. It is due to involvement of the mucous membrane or bony wall of the sinus. There is usually marked stagnation of secretions and the sinus is sensitive to palpation. The pain may be a dull ache or soreness becoming at times more intense.

In chronic sinusitis the headache is more diffuse and often indefinite. Early acute maxillary sinusitis usually causes the sensation of pressure, fullness and distention in the sinus. The pain may be a dull ache or may be neuralgic. In chronic maxillary sinusitis the patient may have no pain to warn him of infection. In fact pain is often not present in chronic cases. In acute frontal sinusitis, headache is the most constant symptom. Acute ethmoid sinusitis can cause pain that is difficult to distinguish from that due to frontal sinusitis. The pain may be a dull pressure or an intense headache. Involvement of the anterior cells causes dull pain between the eyes at the root of the nose. Burning in the eyes, lacrimation and increase of pain when the eyes are used for long periods are typical. The pain is steady, without severe exacerbations. When the posterior ethmoid cells are involved there is temporal, occipital or parietal headache, which is increased by using the eyes. Pain is most often present along the first, and at times the maxillary, division of the nerve, causing pain in the face, which may be confused with that of an antral lesion or tic douloureux. In acute sphenoid sinusitis the pain may be an intense sensation of pressure deep in the head, in the posterior half of the head or behind the eyeball over the vertex, just behind the mastoid process and even in the middle ear. The pain in chronic sphenoid sinusitis is unreliable. Most often it is a feeling of pressure and fullness deep in the head and occipital region, with sometimes stiffness of the neck. Pain in the vertex or temple is frequently present.

Pseudo-Anaphylaxis Following Injection of Benzene
—Steiner produced fatal pseudo-anaphylactic shock in guinea-pigs and other species by repeated intramuscular injection of benzene and related chemicals. Death was due to bronchospasm. Similar reactions were caused by the inhalation and the intravenous injection of benzene in animals who had had no previous experience with the drug. The spasm was not relieved by epinephrine or atropine. It appeared quickly and disappeared with equal rapidity after forced ventilation of the lungs. Repeated intramuscular injections were necessary not to cause a state of true allergy, but to produce an area of inflammation from which the benzene at subsequent injections

was absorbed in sufficient amounts to produce a bronchospasm. The author suggests that the bronchospastic action of benzene shown in these experiments on animals possibly applies to human bronchi and offers an alternative explanation for these acute deaths in man. In view of these results the use of intramuscular benzene injections in the treatment of bronchial asthma, as reported recently by Kairiukstis, should proceed with caution.

Mercuric Chloride Poisoning Treated by Exsanguination-Transfusion.—Hashinger and Simon report a case of mercuric chloride poisoning in which they employed exsanguination-transfusion. It was done for two reasons. First, as shown by Rosenbloom and others the blood and other tissue juices contain the greater part of the absorbed mercury, so that replacing of the blood will remove the poison in the largest possible quantity. Second, if the blood is replaced in sufficient quantity, the nitrogenous products retained in the body will be diluted and kept at a sublethal level until the renal epithelium can regenerate. In addition to the bleeding followed by transfusions, the patient was given a small amount of sodium thiosulphate for its reported value in neutralizing available mercury. Sodium chloride was given to combat loss of chlorides by vomiting. When the patient was seen seven months after dismissal, examination showed the urine to be entirely negative. The systolic blood pressure was 140 and the diastolic 80 and chlorides 460. Clinically the patient was well.

Sedimentation Rate of Erythrocytes.—It appears to Cherry that changes in the blood sedimentation time are caused by disturbing the fine balance between the cellular and fluid elements in the circulation. Cell volume and the variations of fibrin, euglobulin and globulin in the plasma apparently influence the change of rate. These variations from normal occur in so many pathologic states, thus influencing the settling of the erythrocytes that it is impossible to affix definitely a standard sedimentation rate to any disease. To interpret this test for diagnostic purposes, the cell volume and nitrogen partitions must be determined if it is to be of any value. The sedimentation test alone is confusing. Of two persons having the same disease one will frequently show a sedimentation rate

in the fast group and the other in the slow group. As a prognostic aid it is of slight help. A very rapid sedimentation rate does not by any means indicate a poor outlook for recovery, it indicates that toxic absorption and tissue destruction are progressing so rapidly that production of biochemical changes in the blood stream is taking place, and this causes the imbalance of the sanguineous elements. The leukocyte count or filament nonfilament study in conjunction with the clinical picture is of much greater aid than the sedimentation rate.

Micromethod for Determination of Nonprotein Nitrogen.—The procedure that Irving and Forbes use for the determination of blood nonprotein nitrogen is essentially the same as Folin and Wu's method, except that one-fifth the amount of each solution is used and the tubes are graduated at the 10 cc. instead of the 50 cc. mark. The procedure is as follows. One cc. of blood filtrate is transferred to a Pyrex test tube, 150 by 15 mm., graduated at 10 cc., 0.2 cc. of Folin and Wu digestion mixture is added, and digestion is carefully carried out in the usual manner. Distilled water is then added to the 10 cc. mark the solution is mixed, and 35 cc. of Koch's Nessler solution is added. A standard is prepared at the same time, using 2 cc. of an ammonium sulphate solution (1 cc. = 0.02 mg. normal), 0.2 cc. of digestion mixture is added, diluted to 10 cc., and 35 cc. of Nessler solution is added. The finger tip method is essentially the same as the foregoing. Two-tenths cc. of blood is measured in a special pipet and added to 34 cc. of distilled water in a 15 cc. centrifuge tube, the pipet being rinsed out several times with the diluting fluid then 0.2 cc. of a 10 per cent solution of sodium tungstate is added, followed by 0.2 cc. of two-thirds normal sulphuric acid. After mixing and standing for several minutes, the tube is centrifuged at a moderately high rate of speed, then 2 cc. of the supernatant fluid is carefully digested with 0.2 cc. of digestion mixture and analyzed as described. If desired, the supernatant liquid may be filtered through a small filter paper after centrifuging, but this is as a rule unnecessary.

Milk Sickness—Hardin has seen this disease for the last sixteen years and has treated more than 100 cases. Alcohol seems to have an affinity for the substance causing the disease and there seems to be nothing better as an antidote than alcohol pushed to the point of intoxication. She also finds that gastric lavage duodenal drainage, hypodermoclysis of physiologic solution of sodium chloride and dextrose work extremely well. A majority of patients treated without alcohol in some form or other usually die. The custom of the mountaineers treating it with brandy and honey cannot be dismissed lightly. No difference has been found in the effect of brandy and any other type of alcohol. In man, the principal symptoms are loss of appetite, constipation, pain and stiffness in the legs, languor, fatigue, nausea and vomiting (which may be continuous), the tongue is red the breath smells of acetone, the temperature is subnormal and the blood pressure is low. There is a lump or heaviness felt in the pit of the stomach, which is not relieved by vomiting and is felt until the patient is well. Overheating or violent exercise will bring about an acute stage of the disease, as it does in animals.

 Cyclopropane Anesthesia W. S. Sykes.—p 901

Prolapse Syndrome—Palmer combines the operative procedures of anterior colporrhaphy, vaginal hysterectomy, reconstruction of the hernia of the pouch of Douglas, posterior colporrhaphy and perineorrhaphy for the prolapse syndrome. The operative field is prepared and the perineum is incised back to the anal margin. The nymphae are sutured to the thighs, and traction sutures are inserted in the cervix. The area of vaginal mucosa to be removed is determined (1) of the anterior mucosa, a landmark suture is inserted to mark the upper end of the new anterior vaginal wall, and (2) of the posterior vaginal mucosa landmark sutures are inserted at the site of the upper end of the new posterior vaginal wall. The redundant tissue of the anterior and posterior mucosa and the uterus is removed in one technic. In reconstructing the pelvic diaphragm, the uterine stumps and ovario pelvic stumps are fixed on either side to the upper margin of the new lateral vaginal walls. The cut edge of the peritoneum of the uterovesical pouch are joined to the anterior landmark sutures, thus forming the upper end of the new anterior vaginal wall. The anterior vaginal wall is reconstructed. The redundant peritoneum of the hernia of the pouch of Douglas is removed and the peritoneal stumps are sutured to the posterior landmark sutures, thus forming the upper end of the new posterior vaginal wall. The posterior vaginal mucosa and the perineal body are reconstructed. The author states that the operation requires an hour to an hour and fifteen minutes for its performance, without undue difficulty in the control of unexpected oozing. There is, as a rule, no appreciable shock, and the patients do not have a stormy postoperative period. In general they are sitting up the next day, ready to do justice to their dinner. Toward the end of a week there is usually some vaginal discharge, which clears up readily with douching. The length of stay in the hospital and the convalescent period are the same as that for simple repair operations.

Concentration of Quinine in Blood After Intravenous and Intramuscular Injections—The experiments of Chopra and his associates on monkeys show that, if allowance is made for small variations due to the constantly changing factors in the animal organism, the concentration of quinine in the blood after administration by the oral and parenteral routes runs almost parallel. In some cases the concentration obtained within the first few hours after oral administration was definitely smaller, but the concentration soon rose to practically the level of the parenteral routes. In ordinary cases no great advantage can be claimed for any particular method. The routes selected by the clinician should therefore be what suits the patient best. The clinical condition of the patient is the best guide in deciding what route should be adopted. The oral route is undoubtedly the method of choice in the vast majority of cases. The condition of the tongue is an excellent indication of the state of the

gastric mucosa, in ordinary attacks of malarial fever the tongue is moist and slightly furred and under these circumstances quinine is absorbed very well from the intestine. If the tongue is dry, red and cracked, quinine is absorbed badly and in such cases other means should be adopted. Quinine is generally absorbed readily from the intestine, even in cases of severe malaria complicated by dysentery, quinine has been shown to be absorbed. In those cases, however, in which there is nausea and vomiting, or when the bilious vomiting of malignant tertian infection is present, it is useless to give quinine orally and the parenteral routes should be adopted, the intravenous or the intramuscular route being selected according to the requirements of the patient. As soon as the condition of the gastro-intestinal tract improves, administration by the parenteral routes should be stopped and the drug should be given orally. In view of the possible injury to the blood vessels, muscles, nerves and so on by parenteral injections, this method should not be used for routine treatment of malaria but is especially indicated in acute cases of severe type for as long as the emergency lasts.

Prognostic Significance of Small Flaking or O Agglutinins in Typhoid—Soman states that somatic agglutinins play an important part in the immunology of enteric fevers, and particularly in typhoid. By estimation of the titer during the course of the infection, at critical junctures in the clinical prognosis it is possible to forecast with considerable accuracy the chances of life. It is essential to consider the results of the O Widal test and the clot culture together from the same sample in interpreting the significance of the presence or absence of O agglutinins. Their absence in the second week, combined with the presence of the causative organism in the blood, should arouse grave suspicion as regards the immunologic response of the patient. Absence of O agglutinins in the third week of typhoid with a negative clot culture may be looked on as a natural termination of events. Small flaking or O agglutinins play an inconspicuous part in the serodiagnosis of typhoid, especially in Bombay, and therefore it appears unnecessary to make use of the O agglutination test as a routine measure, provided the combined method of clot culture and H agglutination test is done from the same sample of blood. The incidence of inoculated cases also being small, as compared with other advanced countries, there is little chance of discrepancies in the Widal test by the method of Dreyer. Even in inoculated persons suffering from typhoid it is advisable to follow this combined method of clot culture and Widal test, as then the clot culture will settle the diagnosis irrespective of O and H agglutinins.

Anticancer Bodies in Animals Immune to Homologous Tumor—Lumsden and his associates investigation suggests that in addition to anticancer bodies there may be other factors underlying homologous immunity. They are convinced that the formation of antimalignant cell bodies is at least an essential factor, if not the only one, in tumor immunity. In each of

forty-one immunized rats a high titer of anticancer bodies was demonstrable in the serum at some period between the third and eighth days after the last immunizing inoculation. Since these anticancer bodies are absent from the serums of control normal and tumor rats, it is impossible to resist the inference that their presence is intimately connected with the mechanism of tumor immunity. Their presence and variation in degree in rats with regressing tumors and in rats immunized against normal tissues strengthen this conclusion. The authors' view is that it is the power to produce antibodies rather than their actual presence which is the essential factor in tumor immunity. The antibodies are formed when the immune animal has need of them, for example after an implantation of Jensen rat sarcoma. An immune rat that has not been injected with Jensen rat sarcoma for a period of many weeks has a low titer of antibodies. It is probable that a similar mechanism is the basis of natural tumor immunity. When the blood of an untreated rat of a breed known to be resistant to Jensen rat sarcoma is tested, anticancer bodies are usually not demonstrable. If fragments of a Jensen rat sarcoma are injected into such a rat a tumor appears, but after growing for from five to ten days regression takes place and conjointly anticancer bodies appear in the rat's serum. The significance of the secondary waves of high and low titer is not clear. Probably they depend on several factors, among which the varying amount and frequency of the withdrawals of blood for the tests may be important. Another variable is the proportion of young translucent to more granular and resistant forms of sarcoma cells in the tissue cultures used on a particular day. If many of the young translucent sarcoma cells are present, the titer of the serums tested on that day tends to appear high, since this type of cell is especially sensitive to anticancer bodies.

Bactericidal Properties of Adrenal Extracts—Gordon and Knox report that an aqueous extract prepared from the adrenal, and especially from the medulla, shows marked bactericidal action on a number of organisms if the extract is exposed to air. Solutions of epinephrine behave in almost the same way and there can be little doubt that partially oxidized epinephrine is the chief active constituent of the bactericidal extracts. Too prolonged exposure to air of either adrenal extracts or epinephrine solutions results in a gradual and almost complete loss of bactericidal power. Inactivation of both extracts and epinephrine solutions can also be effected by the addition of blood or serum, or by slow percolation through a layer of washed permutite. The most sensitive of the organisms tested were *Corynebacterium diphtheriae* (mitis, gravis and "intermediate") and *Vibrio cholerae*. Other sensitive organisms were *Bacillus anthracis*, *Staphylococcus aureus* and *albus*, *Corynebacterium Hofmanni*, *Bacillus paratyphosus* A and B, *Friedländeri*, enteritidis (Gaertner), typhosus and dysenteriae (Flexner). Rather less sensitive were *Bacillus coli* and *pyocyaneus*, and still less sensitive were *Bacillus subtilis* and prodigiosus and the streptococci. It is possible, as suggested by Raper, that some substance of the orthoquinone type is produced in the course of the atmospheric oxidation of epinephrine and that this substance is the active bactericidal agent. Morgan and Cooper have shown that several quinones are powerfully bactericidal.

Interrelations of *Corynebacterium Ovis*, *Diphtheriae* and Diphtheroid Strains Derived from Human Nasopharynx—Petrie and McClean state that there is no relationship between the specific toxins that are present in filtrates of broth cultures of *Corynebacterium ovis* and *diphtheriae*. An examination of the toxin-antitoxin relations of *Corynebacterium diphtheriae* Mairs aberrant strain of *Corynebacterium diphtheriae*, the group of aberrant diphtheroid strains described by Barratt, and *Corynebacterium ovis* has shown that these strains possess characters which link them together. The strain discovered by Mair occupies a key position in the group because it has an affinity not only to the typical *Corynebacterium diphtheriae* but to *Corynebacterium ovis* and the aberrant diphtheroid strains of Barratt.

Raising the Virulence of Influenza Bacilli—According to Hoyle the virulence of many strains of influenza bacilli can be raised and maintained indefinitely by intrapleural passage in rabbits. By the injection of cultures of influenza bacilli of

raised virulence intrapleurally in rabbits a bronchopneumonia can be produced consistently, the lesion having a close resemblance to that of human influenzal pneumonia. The results of intratracheal inoculation of influenza bacilli in rabbits and guinea-pigs would suggest that it is probably not possible to produce a spreading tracheal infection in these animals, and, although occasional animals so inoculated may die of septicemia or bronchopneumonia it is probable that severe traumatic damage to the lung is essential before such a result can occur. Rabbits and guinea-pigs develop readily a condition of hemorrhagic edema of the lungs as a result of the introduction of liquids intratracheally so that great caution is necessary in interpreting the significance of pulmonary lesions consequent on such inoculations.

Clinical Features of Hemochromatosis—Sheldon states that the diagnosis of a typical case of hemochromatosis should not give rise to difficulties once the classic triad of enlargement of the liver, pigmentation of the skin and diabetes is recognized. There will always be latent cases in which one or more of these may be absent, and it is then that difficulties may arise. The diagnosis is most difficult in cases that merely show an enlarged liver, without either pigmentation of the skin or diabetes. In such cases one should always look for the presence of the syndrome of sexual hypoplasia and for an abnormal bluish black pigmentation round the epiglottis and larynx. In addition the Rous test should be carried out and a biopsy of the skin performed in order to see whether there is a deposit of hemosiderin in the sweat glands and corium. The presence of the latter feature may be taken as pathognomonic. If in addition to the absence of one or more of the major features these subsidiary ones are all lacking it is unlikely that the case is one of hemochromatosis. The author presents an exception to this statement in a case in which pigmentation of the skin antedated all the other symptoms by a period of years. In such a case the presence of a metallic shade in the pigmentation is suggestive and, once the characteristic nuance has been seen it gives certainty. In such cases the final diagnosis can be substantiated only by the passage of time.

Gonad Stimulating Factor in Urine and Hydatiform Mole—Reeb and his collaborators believe that cases already reported prove that the value of the gonad stimulating factor in the urine of pregnant women is not necessarily always increased even in the presence of a living hydatiform mole. Whether the reverse is true—that it is possible to have an increased value of the gonad stimulating factor in the urine without the presence of a mole—is the subject of their report. Two cases are reported by them. In both pregnant women the uterus was too large to correspond with the last menstrual period, there were repeated hemorrhages for from eight to ten weeks, a negative roentgenogram in one case, the absence of albumin in the urine and toxic signs but there was a highly elevated value of the gonad stimulating factor in the urine. The strong presumptive evidence of hydatiform mole and the necessity of stopping the loss of blood gave sufficient indication for evacuation of the uterus. Actually, no hydatiform mole was present but histologic examination of the placenta showed an exaggerated activity of the ectodermal covering of the villi of molar character in one case and a less marked but also abnormal condition in the other. The authors believe that this eversion of the plasmods of the Langhans cells which is not normally seen in placentas of the fourth or fifth month probably explains the elevated values of the gonad stimulating factor in the urine.

Dissociation of Tubercle Bacillus—As a result of cultural and animal experiments Saenz and Costil conclude that stocks of tubercle bacilli of mammals may be easily dissociated into two types of colonies. The S variant is non tubercle forming and causes inflammatory lesions in the guinea-pig rabbit and hen which recover when small doses are given, while the R variant with the exception of BCG which never produces lesions of generalized tuberculosis is tubercle forming and produces generalized lesions. They succeeded in transforming the R variant of the avian bacillus into S and vice versa. Glycerinized potato for example, is favorable for the slow transformation of S into R. They conclude therefore that the attenuation of virulence of strains of avian bacilli long kept in the laboratories is due to the fact that the initial variant S which always predominates in freshly isolated cultures is replaced by the variant R which is much less pathogenic and whose morphologic characteristics approach that of the bacilli of mammals. The dissociation of human strains was more laborious and it was difficult to obtain several variants. The pigmentation of the chromogenic variant was less intense than that of the avian and was observed only in the colonies of the S variant. The authors believe that their observations on dissociation indicate that all types or varieties of tubercle bacilli are derived from a single primitive stock. The elements of this common specific stock in accomplishing their evolution in one or another sensitive animal give rise to the bacillary

elements of the S variant and terminate in greater and greater predominance of the elements of the R variant. It is by reason of this adaptation that the *varum* bacillus represented essentially by the S variant, is the most primitive and least differentiated type. The bovine type comes next. The human type on the contrary, in which the R variant predominates, is the most narrowly adapted. These facts and conclusions, they believe, throw a new light on microbiologic and clinical facts heretofore difficult to explain.

Temporary Sterilization by Biologic Method.—Schteingart and Peralta Ramos obtained satisfactory results in 80 per cent of their cases by the administration of four subcutaneous injections of dead spermatozoa of sheep given at intervals of two days. The first injection contains thirty million dead spermatozoa, the second twice as many as the first, the third twice as many as the second, and so on in multiple proportions. Neither local nor general reactions, worthy of consideration, are observable. The injections of large doses of spermatozoa do not alter the results. When the treatment is given for the first time it produces sterilization for from six to fifteen months, but the duration of sterility becomes shorter as the treatments go on. Conception is resumed under normal conditions whether the treatment has been given one or more times.

Goiters at Puberty.—Del Castillo and Argonz say that different types of goiter (even those of the type of toxic adenoma) are observed at puberty. The prognosis of hyperthyroidism is more serious at puberty than if the condition appears during the adult age. The articles reported on the functional interrelationship between the anterior lobe of the hypophysis, the gonads and the thyroid are of importance. The origin of puberal colloid goiter may be traced to a scanty content of iodine in drinking water if the patients live in the mountains and to an excess if they live on the prairies. Puberal goiter should be classified, according to the variations of the basal metabolism in the following types: (1) goiter with normal basal metabolism (colloid type); (2) goiter with increased basal metabolism (type of toxic adenoma); and (3) goiter with decreased basal metabolism (type of thyroid insufficiency without myxedema).

Glycogen in Placenta.—Guthmann and Bohme examined surgical specimens for the glycogen content of the fetal and maternal portions of the placenta during the different months of the gestation period. They found that the glycogen content in the maternal portion decreases as the pregnancy progresses while in the fetal portion the opposite is the case. With the

exception of the blood corpuscles, particularly the leukocytes and lymphocytes, glycogen is present in all the cells of the placenta, but there are sites of predilection. In the maternal portion the decidua and the adhering portions of the uterine mucous membrane contain the largest amounts of glycogen, while in the fetal portion the glycogen is present in large quantities in the layer of Langhans. The syncytium contains little glycogen, the stroma more. In the stroma there are two different types of deposits, those of the connective tissue and those of the lymph channels. In this manner the arrangement of the glycogen is linear in the villi. The placental vessels contain from the beginning, particularly in the muscle portions and the connective tissue portions, considerable amounts of glycogen, and they increase further with advancing pregnancy. A direct transfer of the glycogen in the maternal tissue to the fetal tissue was not demonstrable; thus the transfer may have taken place only by resynthesis.

Determination of Sex of Offspring.—Schumacher evaluates the various theories of the determination of the sex of the offspring. He shows that the theory accepted by Hippocrates and Galen, namely that the products of the gonads of one side produce male and of those of the other side female offspring, have been disproved by the fact that in unilateral castration children of both sexes have been born. The dietetic hypotheses, according to which the diet of the mother exerts an influence on the sex of the offspring, could not be corroborated. The influence of the age of the parents on the sex of the offspring is, if present at all, so slight that it is of no practical significance. Siegel's theory that the fertilization of young ova produces girls and the fertilization of old ova boys, does not correspond to the present knowledge about the duration of the viability of the ovum and the sex determining factors of the spermatozoa. The influence exerted by the term of cohabitation on the incidence of male and female births is still in dispute. Modern hereditary science and zoology maintain that the sex of the fetus is determined by the spermatozoa, stating that there are male and female spermatozoa, but only one type of ova. The author investigated the observations of Unterberger (*Deutsche med. Wochenschr.* 56: 304 [Feb. 21] 1930, abstr. *THE JOURNAL*, May 3, 1930, p. 1451), that alkalization of the vaginal secretion would produce male offspring. However his studies on human subjects or on animals did not corroborate Unterberger's work. Moreover, the author considers the use of this method inadvisable in human subjects, since the chemical alteration of the vaginal secretion may result in an impairment of the offspring. The attempt to modify the sex of the fetus by treating the mother with sex hormones has so far only theoretical interest. The author is conducting experiments for the clarification of this problem.

Hanganatzu-Deicher Reaction During Childhood.—Dudas points out that Hanganatzu and, independent of him, Deicher observed that, following the parenteral administration of heterogenic serum, human blood serum agglutinates certain heterogenic erythrocytes, particularly those of sheep, horses, hares and guinea-pigs. Especially noteworthy is the high agglutination titer toward the erythrocytes of sheep after the person has received horse serum parenterally. Other authors found that the Hanganatzu-Deicher reaction is strongly positive, particularly in monocytic angina. Dudas studied the Hanganatzu-Deicher reaction in nurslings and children. The test was made as follows: To 1 cc. of serum, inactivated by heating for fifteen minutes in a water bath at 56° C., 1 cc. of physiologic solution of sodium chloride is added. Then 1 cc. of this mixture is withdrawn and placed in another test tube, which contains already 1 cc. of physiologic solution of sodium chloride and the series is continued in this manner. Now 0.5 cc. of fluid is removed from each tube and is replaced by 0.5 cc. of a 5 per cent suspension of sheep corpuscles. Finally 1 cc. of physiologic solution of sodium chloride is put into each tube.

so that they all contain 2 cc. of fluid. After the contents have been mixed thoroughly the whole series is placed in the incubator for two hours and then for twenty-four hours in the icebox. The results are read on the following day. If the agglutination is visible with the naked eye the agglutination is marked ++, whereas microscopic agglutination is marked +. The reaction is considered positive if agglutination is perceptible in a dilution of 1:8 and higher. Cases in which only the dilutions of 1:4 and 1:8 disclosed agglutination were considered as borderline cases. The author found that, following the parenteral administration of serum and following serum disease, the Hanganatzu-Deicher reaction is positive. The reaction becomes positive from eight to ten days following the administration of serum and may remain positive for several months. During measles after smallpox vaccination and during the exanthem caused by the sodium salt of phenyl-ethylhydantoin, the Hanganatzu-Deicher reaction is positive. The parenteral administration of human blood influences the organism in the positive direction.

"Focal Reactions" in Diphtheria Allergy—Siegl maintains that it must be considered as proved that in the process of immunization against diphtheria there develops in addition to the diphtheria antitoxin, also an allergic alteration of the reaction capacity. The positive reactions that develop on the basis of such an allergic condition have, of course, no connection with a specific diphtheria allergy, however, in their appearance and course they greatly resemble those of specific origin, and consequently it is difficult to differentiate them. In a former report (*Arch f Kinderh* 98:1 [No 1-2] 1932) he described a method that permits a differentiation of such reactions. He describes here a new allergic phenomenon. He observed that if children who had been given injections with Lowenstein's prophylactic diphtheria ointment were given a toxoid injection there developed twenty-four hours after the injection not only a local reaction at the site of the injection and perhaps an increase in temperature but also a large maculopapular exanthem that covered only the region of the injection with the diphtheria ointment, whereas the other portions of the skin remained free from it. This localization proves the connection with the previous injections. The cutaneous reaction is of comparatively short duration, for after forty-eight hours it has either completely disappeared or only slight traces remain. The author considers the phenomenon a flare-up reaction due to the local immunologic processes produced by the toxoid in the prophylactic ointment. These focal changes are in the beginning invisible and become manifest as the result of the toxoid injection. The phenomenon was observed in three out of seventeen children who had been given a toxoid injection after injection with prophylactic diphtheria ointment. The author describes the histories of these children. The intervals between the last injection and the toxoid injection causing the reaction were two, eight and fourteen days. In one of the cases only one injection had been made. Another injection of toxoid eight days later, did not cause a new flare up reaction. The author emphasizes that the elicibility of a toxoid flare-up reaction has no connection with tuberculin susceptibility.

Protein Therapy in Gastric and Duodenal Ulcer—Engel describes his observations on protein therapy of gastric ulcer in seventy cases in which an ulcer had been demonstrated by roentgenoscopy, gastroscopy or clinical examination. Cases presenting adhesions, severe stenosis or nervous disturbances have been excluded from the protein therapy. The injections of the protein preparation were begun after dietetic treatment had failed. The injections were made intravenously beginning with

doses of from 0.2 to 0.4 cc. and gradually increasing to 1 or 2 cc. They were given at intervals of from three to four days. A series consisted of from four to eight or, rarely, twelve injections. In almost half of the cases a slight increase in temperature resulted from the injections. High fever, necessitating interruption of the injections, developed in two cases. Local reactions in the form of gastric pains and increased hemorrhages were not observed. In the majority of cases the gastric pains decreased after the first injections. At the same time the weight of the patients increased and in some cases the roentgenogram revealed improvement. Complete cure was effected in 19 per cent of the cases, great improvement, that is, complete freedom from symptoms, was observed in an additional 39 per cent of the cases, slight improvement was noted in 30 per cent of the cases, and in only 12 per cent was the protein therapy a complete failure. These results compare favorably with those of other therapeutic methods, and the author thinks that ulcers which do not yield to dietetic treatment should be subjected to protein therapy before surgical treatment is resorted to.

Soy Flour in Treatment of Urinary Infections, Eczema and Diabetes—In an analysis of various flours, Becker shows that soy flour differs from other flours in that it is rich in proteins and fats and almost free from starch. The carbohydrates of soy flour appear in the form of soluble saccharose, and the flour contains large amounts of lipoid (lecithin) and minerals. Because of this composition the soy flour has therapeutic value in urinary infections, eczema and diabetes. Its action is due to the large quantities of bases it provides for the organism, for the high mineral content of the soy bean increases the alkalinity of the urine within a short time to a pH of 8.4 and more. This alkalotic alteration is already effective in the internal metabolism and is not caused by ammonia cleavage of the urea in the urine by urease, a ferment of the soy bean. The large amount of minerals and a number of other substances contained in the soy bean effect in eczema a reduction in the inflammatory process and protect the overtaxed peripheral capillaries. Moreover by providing a high caloric food of plant origin and thus permitting the exclusion of animal foods, particularly milk, the allergic factor is largely excluded in the eczemas of nurslings and children. The anti-inflammatory action and the alkalinization of the urine, which in turn restricts the growth of colon bacilli, are the effective factors in pyuria. In diabetes the basic salts of the soy bean neutralize the excessive organic acids and thus reduce the acidosis. Bread prepared from soy flour is an adequate substitute for wheat bread in the diet of patients with diabetes mellitus. The use of this bread in the diet reduces glycosuria and also the blood sugar values.

Exophthalmic Goiter—According to Voss, iodothyroglobulin is the specific secretion of the thyroid since it is the only substance so far isolated capable of producing all the symptoms caused by the administration of the thyroid substance itself. Thyroxine is only one of its main constituents. Thyroxine and di-iodothyrosin are the essential constituents of the thyroid secretion. They combine in the thyroid with an albumin to form iodothyroglobulin. Di-iodothyrosin exerts a depressive effect on the action of thyroxine. The author examined thyroid secretions from normal and diseased thyroids with the aid of a spectrograph to determine whether there exist differences in the light absorption, thus demonstrating structural changes in the molecule. Iodothyroglobulin obtained by the method of Oswald from normal thyroids from goitrous thyroids and from exophthalmic thyroids were submitted to spectrographic examination. No difference was noted in the light absorption by the iodothyroglobulin obtained from normal thyroids and from colloid goiters. The curve representing the light absorption of the secretion from exophthalmic thyroids was

different from that of normal thyroids and of colloid goiters. This suggests that the molecular structure of the iodothyroglobulin of an exophthalmic thyroid differs from that of the normal thyroid and from that of a colloid goiter. Ordinary hyperfunction of the thyroid is easily demonstrable both in clinical cases and in experiment. The question of whether ordinary hyperthyroidism can develop into a genuine exophthalmic goiter has not been answered. The present concept is that the difference in the two forms depends on the rate of evolution, in the course of which a mere hyperfunction passes into a state of dysfunction. Histologically pure hyperthyroidism is represented by a hypertrophy of all the anatomic elements of the gland, including the colloid. In exophthalmic goiter, on the other hand, the colloid is greatly diminished and the epithelium undergoes a characteristic hyperplasia. At present there exist many cases in which, owing to administration of iodine, the typical alterations in the colloid and in the epithelium cannot be demonstrated. The author admits that there are mixed cases in which both the histologic characters of hyperfunction and of exophthalmic goiter exist side by side. The clinical manifestations of hyperthyroidism may be duplicated by thyroid feedings. The symptoms common to the two are tremors, rise in basal metabolic rate, loss of weight, irregular heart action, hypertrophy and degeneration of the heart muscle. Exophthalmos is not present. The characteristic symptoms of exophthalmic goiter cannot be reproduced by thyroid feeding, this applies particularly to such symptoms as exophthalmos and increased vascularity of the gland as evidenced by bruit over the vessels of the gland. The onset is more acute and all the symptoms are more pronounced in exophthalmic goiter. The author found that, whereas chronaxy in normal people is twice as long in extensors as in the flexors, this relationship is disturbed in exophthalmic goiter. On the basis of his experiments the author differentiates between exophthalmic goiter and hyperthyroidism. He assumes that the first is caused by dysfunction of the thyroid while the second is caused by hyperfunction.

Miliary Tuberculosis Following Curettage—Bungele describes a case of tuberculous endometritis that developed following an exploratory curettage. A woman, aged 28 had given birth to a living child in 1932. In August 1933 she had an inflammation of the ovaries and in December she complained of pains in the abdomen and of occasional hemorrhages. The family physician diagnosed a pregnancy in the fourth month. In January the woman had an abortion, but the physician was not consulted until two days later when she developed fever. The physician scraped the uterus with a dull curet, but the material obtained was not examined. Following this curettage the woman developed a parametritis and since this time her temperature was always increased. An exacerbation occurred at the end of February and the patient died several weeks later. Postmortem examination revealed a caseous tuberculosis of both uterine tubes, tuberculosis of the mucosa of the uterus, numerous tubercles in the intima of the small vessels of the endometrium, a few tubercles in the intima of the ovarian vein, acute miliary tuberculosis, tuberculous meningitis, miliary tuberculosis of the lungs and spleen, disseminated small-noduled tuberculosis of the peritoneum, multiple tubercles in the kidneys and the liver, and dilatation of the entire heart. The increase in temperature following curettage indicates the author says, that this intervention was made on a uterus already infected with tuberculosis and the curettage led to a massive invasion of the blood stream by tubercle bacilli. The author shows that the case corroborates the opinion expressed by Ribbert and Huebsch

mann, who stated that the vascular tubercle is insignificant in the hematogenic dissemination of tuberculosis. The lack of generalized infection of the organism with tuberculous virus in case of genital tuberculosis also seems to play an important part in the development of miliary tuberculosis. The author emphasizes that, if uterine tuberculosis is certain, curettage should never be resorted to.

Melanosarcoma of Brain, Pigmented Nevi of Skin, and Neurofibromatosis of Cutaneous Nerves—Bjorneboe says that the concurrence of these three disorders is rare. The patient, a man aged 37, died with symptoms that indicated a rapidly growing cerebral tumor. Postmortem examination revealed a melanosarcoma in the right cerebral hemisphere. On the face and the upper and lower extremities there were numerous brown spots, many of them with hair growth and only partly elevated above the level of the skin. The trunk and the upper extremities had a furlike hair growth, which was sharply and symmetrically defined on the chest. Over the gluteal muscles the skin showed changes indicative of elephantiasis. The skin showed two anomalies—nevi and neurofibromatosis—and the problem is whether these two conditions are related. The concurrence of extensive nevi of the skin and of the neurofibromatosis of the cutaneous nerves in the nevi has been described by Berblinger. The concurrence of Recklinghausen's disease and of cutaneous nevi has been reported repeatedly, particularly by Masson, who maintained that the cells of a nevus are connected with the cells of the Wagner-Meissner tactile bodies. He considers the piles of nevus cells as syncytia that are connected below with nerves and above with cells of the epidermis. These syncytial structures frequently assume forms that resemble the Wagner-Meissner bodies. Masson was able to detect neurofibrils only in the beginning portions of these syncytial structures, but he believed that they were of the same origin as the Wagner-Meissner and the Merkel-Ranvier cells. In attempting to apply this theory to this case, the author was unable to detect neurofibrils in the cutaneous preparations. However, threads were detected that were probably of a nervous nature but had undergone neurofibromatous changes, and it is significant that the threads were partly melanotic. This supports the opinion that the cells are ectodermal (capable of forming pigment). Moreover, this makes it appear likely that the pigmented cells that are located higher up in the cutis are of nervous origin. This one case does not permit a conclusion about the genesis of all nevi. Nevertheless it is a further corroboration of Masson's theory.

Examination of Urinary and Biliary Calculi by Ultraviolet Rays—Faber observed that urinary and biliary calculi show fluorescence in filtered ultraviolet rays. The urinary calculi showed on exposure to ultraviolet rays a greater number of layers and a more manifold coloration than they did in ordinary light. From the color of the fluorescence it may be concluded of what substances the calculus is composed. The fluorescence of urinary calculi is due to the substances that by adsorption are combined with the salts, which form the calculi. Since bile pigments interfere with fluorescence, it is impossible to deduce conclusions about the composition of biliary calculi from the nature of their fluorescence.

The Corpus Luteum Hormone and Periodic Sterility and Fertility—Glaser and Haempel describe a method that makes possible a quantitative determination of the corpus luteum hormone in the urine. The urine is subjected to electrolysis and heat concentration and the substance thus obtained

is tested on female minnows. It was determined that corpus luteum hormone (male hormone), perhaps augmented by hormone of the suprarenal cortex, is present in the urine of women in all stages of the cycle, and also in the urine of young girls and of women of the menopausal age. In young girls and in women of the menopausal age the elimination keeps within comparatively narrow limits, but in the latter certain fluctuations are noticeable which apparently correspond to the former cycle. In women of the propagative age the elimination of the female sex hormone is greatest at the time of ovulation, while the largest amounts of corpus luteum hormone (male) are eliminated during the period of menstruation. At this time the daily average is 3000 fish units. After that its excretion decreases apparently (slower in long cycles, faster in short cycles) until the time of ovulation and during the last days of the cycle it remains at a daily average of from 300 to 600 fish units. Thus it is impossible to consider the activity of the corpus luteum as restricted to certain periods. A superordinated organ, either the anterior lobe of the hypophysis or a nervous center or both regulate the elimination. At any rate the actions of the corpus luteum are rather complicated and cannot be reduced to as simple a system as that suggested by Knaus. The authors believe that the corpus luteum is probably the main cause of the partial failure of the theories of Knaus. They assert that in all stages of the cycle and in all ages the urine contains hormones which promote the growth of the ovipositor of female minnows; however the elimination is not sufficiently regular to be suitable for test purposes.

Serologic Investigations in Multiple Sclerosis.—Sachs and Steiner admit that the etiology of multiple sclerosis is not fully understood as yet. However since many investigators are of the opinion that it is the manifestation of an infectious process the authors felt justified in conducting a search for antibody-like factors in the serum of patients with multiple sclerosis. They employed a complement fixation test and used alcoholic extracts from diseased central organs (brain and spinal cord) as reagents. They gained the impression that the serum of patients with multiple sclerosis actually has a special reactivity to the extracts from brains with multiple sclerosis. They reproduce several tables of the results of their tests which indicate that there is a noticeable difference in the behavior of the multiple sclerosis serums and the control serums. Moreover in some patients with multiple sclerosis who had a positive reaction a remission in the disease process was followed by a change to a negative reaction. The positive reactions were most frequent during the acute stage of the disorder. In an evaluating summary of their studies the authors show that it is as yet impossible to give a definite estimate of the value of their serologic studies but their observations so far indicate the existence of a serologic change that is comparatively frequent in patients with multiple sclerosis.

Weltmann's Serum Coagulation Reaction in Tuberculosis.—Oigtländer points out that Weltmann's serum coagulation reaction is helpful in the diagnosis and prognosis of tuberculosis. This new reaction permits a decision as to whether the tuberculous processes in the organism are of the exudative or the fibrous type. He describes the technic of the Weltmann serum coagulation reaction and describes his own experiences with the method. Weltmann had found that a number of tubercle processes are accompanied by a narrowing of the coagulation band that is by a deviation to the left. That the fever itself was not the cause of the deviation to the left was proved by the fact that in artificially induced fever the flocculation band was normal. Deviation to the left was observed in diseases of inflammatory character (exudation) such as pulmonary tuberculosis, pleurisy with effusion, the acute stage of articular rheumatism, suppurative processes and exudative malignant pulmonary tuberculosis. The coagulation band shows no deviation to the left without an inflammatory that is an exudative process. The degree of deviation runs parallel with the severity of the process. As the inflammatory process improves the coagulation band returns to normal. A deviation to the right or a widening of the coagulation band was observed by Weltmann in diseases of the hepatic parenchyma in cardiac decompensation with stasis and in fibrous forms of tuberculosis. The author performed the Weltmann serum coagulation test on 400 inmates of a sanatorium for tuberculous patients and found

that the coagulation shows a deviation to the right in fibrous and cirrhotic forms of tuberculosis. In inflammatory processes of pulmonary tuberculosis, in cavernous progressive conditions with exudative processes and in caseous pneumonic pulmonary tuberculosis, a deviation to the left is noticeable. Pulmonary disorders in which exudative and fibrous processes concur cannot always be clarified by Weltmann's reaction. In pleural exudates the coagulation band runs practically parallel to the course of the disorder. Since the Weltmann serum coagulation reaction does not always give reliable results it is advisable to combine it in doubtful cases with the determination of the sedimentation speed of the erythrocytes.

Influence of Metal Compounds on Growth of Bacteria.—Haase tested the foils of copper, brass, tin, aluminum and silver for their bactericidal action and compared it with that of two silver compounds, silver manganite and the silver salt of thiocellobiose. The tests were made with agar plates. The author points out that silver foil has been known as an effective bandage for wounds, but he found that its bactericidal power is rather slight. The foils of other metals exert hardly any bactericidal power on organisms on the agar plate. The silver compounds were found to be much more effective. The silver salt of thiocellobiose was tested with gauze saturated with a 10 per cent solution of the substance. This gauze proved to have great bactericidal power on the agar plate. The author states that the action of this gauze on wounds has not been thoroughly investigated as yet but since a 5 per cent solution of the silver salt of thiocellobiose has been used for injection without harmful effects it may be assumed that wounds will tolerate the gauze impregnated with the substance. In fact several applications revealed no changes in the course of the development of wounds. Silver manganite proved somewhat less effective on the agar plate than did the silver salt of thiocellobiose; however it was much more effective than the foils of pure metals. The author points out that silver manganite is introduced into bandage materials, catgut and silver foil and that in this form it finds wide application. It has no irritating effect on wounds and it has been used also in the form of powders and ointments. The author admits that the surface antiseptics of a wound is only a small part in the fight against infection.

Hormone Regulation of Chloride in Children.—Török and Neufeld point out that the action exerted by the hormones of the hypophysis and the thyroid on the chloride-water exchange has been repeatedly investigated but that there are a number of other hormones the action of which on the chloride exchange has not been thoroughly studied as yet and so they tested a number of these. They made their studies on forty-one children from 5 to 12 years of age. During the first test period the children received at first a standard diet that provided from 5 to 8 Gm. of sodium chloride daily, and then they were put on a milk diet with a lower salt content. During

the second test period when the children received once more the standard diet they were given daily injections of hormone or glandular extracts. This period lasted generally eight days and after that the children were put once more on a milk diet. The amount of chloride excreted in the urine was determined daily by the method of Russznark. The first tests were made with the antidiuretic hormone fraction of the posterior lobe of the hypophysis. During the first part of the second test period, when the antidiuretic posterior hypophyseal hormone was administered daily, the average daily chloride elimination was greater than during the first period, when a standard diet and no hormone extract, was given. At the time of the milk diet of the second period, an increased retention of chloride was demonstrable. The various sex hormones and extracts were tested on fifteen children. The sex hormone of the anterior hypophysis was tested in four children and the follicle hormone in three, the extract prepared from the entire ovary the corpus luteum hormone, and the estrus stimulating and inhibiting fractions of the corpus luteum hormone in one child each, the testicular extract in three children, and the extract of the mammary gland in one child. These experiments revealed that with the exception of the corpus luteum hormone (entire), of the estrus inhibiting fraction of the corpus luteum and of the mammary hormone, the sex hormones and extracts cause an increased retention of chloride during the time of their administration but after the administration ceases the retained chloride is eliminated. The extract of the pineal body was tested in four children. In these tests no regularity was demonstrable. In experiments with extracts of the thymus and the spleen, an increased chloride elimination was noticeable after the administration of these extracts had ceased. While the thymus extract was given the chloride content of the urine was more or less reduced but while spleen extract was given this was not the case, and in one child the elimination was even increased. In the experiments with the tonsillar extract it was found that, although the chloride elimination in the urine was not reduced during the time of the injection of the extract, it increased after the cessation of the injections. The administration of liver extracts proved without influence on the chloride excretion. The same may be said about the extract of the suprarenal cortex and about insulin. Parathyroid extract produced a considerable chloride retention in two children, while in another child when a less concentrated parathyroid extract was used, this was not the case.

Fluctuations in Immunity in Infectious Diseases — Meyer zu Hörste points out that the resistance of the organism to infections is subject to considerable fluctuations. It happens, for instance, that the disease suddenly develops in physicians and nurses who for years have worked in a scarlet fever department. But not only the resistance to a certain pathogenic organism but also the so called natural immunity is subject to fluctuations. In the course of an infectious disease, it may happen that the defense mechanism fails suddenly. In this event a change must take place in the fluids and cells of the organism which cannot be determined by means of the ordinary methods of examination but may become manifest in the skin or in the visible mucous membranes. The author describes the case of a child, aged 13 months, who developed whooping cough. This became complicated by pneumonia and by cutaneous suppurations in the occiput. Suddenly the condition became more threatening a meningo-encephalitis and a severe occipital ulceration developed. The child died. This case illustrates the sudden loss of the natural immunity. When this took place, not only did the organism lose resistance to the whooping cough, but the disease processes of the skin likewise did not heal. The author thinks that when the infectious process spread to the central nervous system, the natural immunity failed completely. The development of a second infection, for instance the concurrence of diphtheria and measles, may lead to such a complete failure of the natural immunity. The author further reports the history of a child, who because the first vaccination against smallpox had not taken was revaccinated and this time the vaccinia presented the usual aspects. About the time when the formation of the immune bodies had already passed its peak, the child developed whooping cough which took an especially severe course. This second infectious disease influenced the immunization processes against vaccinia

so unfavorably that the immunity was practically lost again. The vaccination scar developed a new reaction. Later the immunity processes became active again and the child recovered. The author points out that in the Spanish literature the suggestion has been made to employ smallpox vaccination for the treatment of whooping cough, but that some Spanish authors have objected to this method. He thinks that his case, in which whooping cough and vaccinia accidentally concurred is an argument against that treatment because the severe course of the whooping cough was the result of the smallpox vaccination that had preceded it.

Roentgenoscopy in Diagnosis of Appendicitis — Klem-schmidt describes his experiences with roentgenoscopy of the appendix in a number of children. He reaches the conclusion that roentgenoscopy with the aid of contrast filling is not suited for the diagnosis of appendicitis. He found that the evacuation time differs widely even in normal appendices, and he thinks that it is largely determined by anatomic and physiologic peculiarities such as the length, position and lumen of the appendix, the intestinal activity and the mode of life. At any rate the isolated filling of the appendix may last 100 hours and even more when the organ is healthy so that a filling that lasts this length of time need not be indicative of a pathologic condition. If filling does not take place, an obstruction of the lumen of the appendix exists, which may be in the nature of mechanical factors (fecal concretion, fixation or bending), of inflammatory changes (swelling of the mucous membrane) or of severe contraction of the musculature of the antrum. A diseased appendix may prevent filling partly or completely or may cause an unusually prolonged filling. Differences in the duration of the filling of the cecum and the appendix are unsuited for the diagnosis of a disorder of the appendix. The author was unable to corroborate the statement that the evacuation time becomes normalized after the inflammation of the appendix has subsided.

Reactivation of Senile Human Ovaries —Waldeyer points out that Zondek and Aschheim and several other investigators succeeded in bringing about regular estrus in old animals by the administration of the hormone of the anterior hypophysis. Attempts were made by Tschertok and Penkow and by Westman to reactivate senile human ovaries by injecting urine or blood from pregnant women. In order to be able to determine the efficacy of the experiment they gave these injections to women of the menopausal age, who had to undergo operations on the genitalia. Tschertok and Penkow employed pregnancy urine and obtained negative results in all except one of the cases and in this one estrogenic substance had been administered in addition to the urine. Westman, who used pregnancy blood in two cases, observed what he considered a reactivation of the ovaries and he concludes from this that it is possible to reactivate the ovaries of women of the menopausal age by injecting the sex hormone of the anterior lobe of the hypophysis. The author thinks that a number of his observations can serve as controls of Westman's experiments, for he examined the ovaries of women of the menopausal age without previous injection of gonadotropic substances. Observations in seven cases convinced him that the development of a follicle to the stage of a young corpus luteum together with the corresponding changes in the uterine mucous membrane, can take place during the menopause, although no hormone has been administered. Moreover, he points out that Robert Meyer observed even a fully developed corpus luteum. The author concludes that he does not care to deny the possibility of a modification of the resting follicles in the ovaries of women of the menopausal age but he wants to point out that great precaution is necessary.

in the evaluation of experiments on the action of the gonadotropic hormone of the hypophysis on human ovaries

Tumor of Sublingual Gland and Pregnancy—Luh thinks that pathologic changes of a morphologic nature in the salivary glands, during or as the result of pregnancy, are rare. He admits that more than two decades ago certain relations were detected between changes in the salivary glands and the genital organs but a causal connection was not discovered. Even the ptyalism of pregnancy has as yet found no causal explanation. Madruzza made studies on pregnant rats and mice and found the interstitial tissues of the salivary glands unchanged but noted that the acini of the parotid and submaxillary glands were in a state of increased function, while those of the sublingual gland were at rest. The excessive enlargement or swelling of one or the other of the salivary glands during pregnancy is extremely rare and for this reason the author feels justified in reporting the case of a woman who gave birth to a normal girl and who had a tumor in the anterior portion of the neck. The growth reached from the region of the thyroid cartilage to the third rib and was oval. Palpation indicated that the growth was a slightly fluctuating cyst. A cone-like process about 10 cm in length branched off from the main tumor in the direction of the submaxillary angle. Pressure on the tumor resulted in a swelling of the branch directly below the submaxillary angle. The entire submental region was lowered in the form of a double chin. Inspection of the oral cavity disclosed a transparent, cystic growth in the region of the sublingual caruncle. There seemed to be no communication between the tumor in the neck and this cyst. The tumor of the neck remained unchanged during the period of expulsion of the fetus. Until the anamnesis was taken it seemed that there was no connection between the tumor and gestation. The woman stated that her first pregnancy terminated in the sixth month the fetus being dead. On the third day following the abortion a tumor developed in the mouth and became so large that she could be fed only fluids introduced by means of a tube. On the fifteenth day following the abortion the physician punctured this tumor and a watery fluid was discharged. The patient recovered completely the growth having entirely disappeared. At about the middle period of the second pregnancy, which was carried to term a tumor formed at the right submaxillary angle and the floor of the mouth felt somewhat elevated. During the puerperal period the tumor as well as the swelling of the floor of the mouth disappeared but later the woman noticed that during the menstrual periods the swellings returned in a milder form and then disappeared again. At the end of the third month of the third pregnancy she observed the reappearance of the swelling at the submaxillary angle and on the floor of the mouth and shortly after that the tumor formed in the anterior part of the neck. This anamnesis reveals the close connection between pregnancy and the development of the tumors. One month after the termination of the third pregnancy, the tumor was punctured. The contents a jelly-like substance about 90 Gm in weight, were examined. Shortly after that the cyst was likewise removed and examined. Although the examinations revealed neither a neoplasm nor an inflammatory tumor, it must nevertheless be assumed that the tumor developed on the basis of a chronic interstitial inflammation with subsequent retention of the secretion.

*Pathogenesis of Gout. I. A. Golyanitskiy—p. 1477

Pathogenesis of Gout—Golyanitskiy says the experimental production of gout has not been accomplished. Clinical observation still remains the main source of information in the malady. Visceral gout is frequently observed in chickens and

in hens. The essential pathologic characteristics of gout in birds and associated renal and hepatic lesions suggest a similarity with gout in man, although the process cannot be viewed as identical. Atmospheric conditions and temperature play an important part in the pathogenesis of gout, and dietetic regimen plays an even greater part. The significance of the various components of the diet, such as albumins, carbohydrates, fats and minerals, may be positive or negative depending on varying conditions. Deficiency in vitamins, minerals or ferments with the associated acidosis may act as the deciding factor. Prophylaxis of gout should be directed toward a favorable alteration of the enumerated factors and toward combating acidosis. The therapy should be many sided and, besides the diet, should utilize all the means of increasing the oxidating processes and of raising the alkali reserve.

Pathology of Psittacosis in Man—Mansens reviews the conditions that have been described in the organs of man in psittacosis and presents a new case of the disease with photomicrographs. The typical psittacotic lung is characterized by a lobular confluent pneumonia. The cut surface is gray or red, smooth and moist but not granular. There is a highly varying exudate, which may consist of a serous fluid, generally with little fibrin, many or few large mononuclear cells, and few leukocytes. Undoubtedly the large cells are partly desquamated cells of the alveolar lining and partly macrophages. The interstitium may be thickened. The pleurae may have a light fibrinous membrane, but most frequently they are smooth. The bronchi are often empty or contain only a serous exudate with little cells. The author attributes the predominance of leukocytes to secondary infections, which commonly occur. The liver and the kidney show epithelial degeneration. Sometimes focal necrosis is seen in the liver. The reticulo endothelial system of the spleen is swollen. The same may occur in the liver. In several organs hemorrhages may be observed. The author concludes that whereas the pathologic picture of psittacosis supports its diagnosis, it is not sufficiently specific to replace the clinical and epidemiologic picture.

Infections with Streptococcus Epidemicus—In twenty-two cases of infections due to Streptococcus epidemicus during the winter of 1933-1934 Thjøtta and Henriksen found that the microbe was in all respects identical with the Streptococcus epidemicus described by Davis and Rosenow in 1912. Biochemically the strains were uniform, all were human strains. Serologically slight differences demonstrable only by absorption and agglutination appeared between the strains from Oslo Akcr and the three Røros. The strains are all ascribed to the same source of infection, which, however, was not confirmed. Clinically the cases ranged from more or less severe inflammations of the skin to septic sore throat, erysipelas, bronchopneumonia and sepsis. Four cases were fatal. Comparison between these strains and the angina streptococcus from the epidemic of milk borne septic sore throat in Oslo in 1908 described by Ustvedt and investigated by Holth indicates that the microbes from 1908 and from 1934 are of the same type.

TRAUMA AND THE NERVOUS SYSTEM

WITH SPECIAL REFERENCE TO HEAD INJURIES AND
A CLASSIFICATION OF POST-TRAUMATIC
SYNDROMES (ANALYSIS OF ONE
HUNDRED CASES)

I S WECHSLER, M D
NEW YORK

The subject of trauma and the nervous system, more particularly trauma to the head, has undergone considerable revision in recent years. More accurate investigation of the pathologic changes of concussion of the brain, increasingly objective clinical studies and the introduction of encephalography have enriched with facts a subject which hitherto was to a large extent in the realm of opinion. None the less there is still considerable dispute among competent neurologists as to what is and what is not objective evidence, and opinion, if not bias, still bridges gaps which should be filled in with facts.

The relation of trauma to the nervous system and its sequels is complicated not alone by difficulties of diagnosis but by medicolegal problems and by difficulties in medical and social management. The problem is further complicated by the fact that most human beings are easily suggestible and that trauma occasionally offers an escape from difficulties in life which are not always easy to face. Added to these are the modern industrial compensation provisions, the occasional bad management on the part of lawyers and physicians, and the general encouragement to litigation on the part of almost everybody. Finally, the frequent insistence on positive statements, which the neurologist cannot always make, and the conflicting opinion of experts taking sides in doubtful cases add extraneous difficulties to a question which is sufficiently complex in itself and which the neurologist can hope to solve only on its neurologic and psychiatric merits.

It is extremely difficult to dislodge erroneous views and old concepts made respectable by medical and lay tradition, thus, for example, the question of fracture of the skull. It is well known that a person may receive a severe blow to the skull and sustain no fracture and no injury to the brain, he may receive a comparatively light blow and sustain both fracture of the skull and injury to the brain, he may sustain a fracture and no brain damage, he may have no fracture and yet have severe injury of the brain. A person may

even receive no direct blow and still suffer grave cerebral injury. All these facts are well known to neurologists. They have insisted on the importance of injury to the brain, the meninges, the cerebral and meningeal vessels or the cerebral nerves, and on the significance of prolonged unconsciousness and not on whether there was or was not a fracture, yet most people still continue to stress and to attach undue significance and importance to the fracture itself.

As the subject of trauma and the nervous system is far too big for a brief paper, I shall devote the major part of this paper to a discussion of trauma to the head and to a classification of the syndromes which may subsequently develop. The discussion is based on the study of 100 consecutive, unselected cases of head injury culled from a general neurologic office practice. I believe that the importance of this series, even though the number is admittedly small, derives from the fact that it represents a cross-section of all types of cases seen after the acute stage was over and therefore permits some general conclusions. Before I proceed with the analysis of the cases and the classification of syndromes, however, it may be well to lay down a few general principles.

GENERAL CONSIDERATIONS¹

Traumatic cases may be divided into the following classes

1 Cases in which injury to the nervous system is the direct and immediate result of an accident. Following a fall or direct or indirect blow to the head there may be unconsciousness, fracture of the skull, intracranial bleeding, severe injury to the brain and cerebral nerves, paralyzes and other sequels. A similar accident may result in such conditions as a dislocation or fracture of the spine, crushing of the spinal cord, hemorrhage into the meninges or hematomyelia. Various forms of trauma, such as stab wounds and fracture of bones, may cause peripheral nerve injuries. Emergence from chambers filled with compressed air may give rise to the myelopathy known as caisson disease. Contact with high voltage current, if not immediately fatal, may lead to prolonged unconsciousness, convulsions, transient or permanent paralysis, and a host of mental and psychic sequelae. Cases falling into this group present no debatable points, certainly no doubt as to the causal relationship of the trauma to the clinical syndrome. There may arise the questions of responsibility and contributory negligence, both of which are obviously dependent on the veracity and competence of witnesses, but neither has anything to do with the purely medical aspects of the case.

Read before the Section on Nervous and Mental Diseases at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

¹ Some of these have been published previously in the author's *Textbook of Clinical Neurology*, Philadelphia, W. B. Saunders Company, 1931.

2 Cases in which the nervous system shows the effects of trauma several hours or a few days, sometimes a number of weeks, after the receipt of the injury. Meningeal hemorrhage may occur a day or two after a blow to the skull, apoplexy may follow several days after injury to the head, meningitis may set in days or weeks after fracture of the skull, abscess of the brain may manifest itself days, weeks or even months after a brain injury, a subdural hematoma may be diagnosed months after the receipt of a blow to the head. This group of cases presents no debatable points, though there is no unanimity of opinion on the question of apoplexy, particularly regarding the condition known as late apoplexy.

TABLE 1—*Duration of Symptoms*

Duration	Number of Cases
1 to 6 months	29
7 to 12 months	24
1 to 2 years	21
2 to 3 years	11
3 to 6 years	15

3 Cases showing no immediate effects of injury to the brain, but only well attested sequels. Convulsions, particularly focal epilepsy, may set in months or years after injury to the head and brain, optic atrophy or spinal cord degeneration may appear months after contact with electric currents, ulnar paralysis may result from late callus in fracture of the internal condyle months or years after the injury. An arteriovenous aneurysm may develop a very long time after fracture of the skull, while mental deterioration is known to occur in children who had brain injuries. There is no disagreement as to facts, but there may be some difference of opinion as to interpretation.

4 Cases in which disturbance of the brain follows immediately or within a reasonable period after an injury to the head, but the trauma alone is not responsible. Thus, a man with undetected incipient dementia paralytica may receive a blow to the head and the fulminating disease may rapidly develop, then gallop on to a fatal termination. An alcoholic person or one with cerebral arteriosclerosis may rapidly deteriorate after a blow to the head. A person may fall during a convul-

TABLE 2—*Duration of Unconsciousness*

State	Number of Cases
No unconsciousness	23
Momentary unconsciousness	12
Unconscious for from 5 to 15 minutes	16
Unconscious for from half an hour to several hours	22
Unconscious one day or longer	12

sion and receive a brain injury which aggravates the convulsive state and leads to deterioration. Such traumas may be said to aggravate or possibly precipitate but not to cause disease of the nervous system, and differences of opinion are justified regarding the group.

5 Cases in which there is the question of the relation of head trauma to infectious and other diseases of the nervous system. The relation of head trauma to such infections and diseases of the nervous system as encephalitis, meningococcal meningitis, brain tumor and paralysis agitans is highly debatable. Parker and Kernohan² have thoroughly disposed of the question of gliomas and head injury.

6 Cases with no early or late evidence of brain injury subsequently presenting subjective complaints. This most important group consists of patients who, following the receipt of an injury to the head, with or without unconsciousness, show few or no organic signs at the time of the accident and no evidence of brain injury subsequently yet present a host of subjective complaints, a number of essentially mental signs and symptoms which incapacitate the individuals. This is the most debated group of all, and it is the one that I would discuss at greater length.

ANALYSIS OF ONE HUNDRED CASES

The records under analysis are of those of patients referred to me by physicians and lawyers. Sixty-two³ were litigation cases, wherein a medicolegal opinion alone was requested, thirty-eight patients came for diagnosis and treatment. Thirty-one patients were females and sixty-nine were males. Practically every occupation and every walk of life was represented, the majority being employees. The youngest patient was 3 years old, the oldest was 69, the average age was 37, only four were below 10, seven were between 10 and 20, and eighty-nine were over 20. The duration of the symptoms from the date of the injury to the time the patients came under observation (table 1) ranged from one month to six years. In eighty-nine instances the symptoms dated back to the time of the injury, in only eleven cases was there a so-called incubation period.

TABLE 3—*Types of Organic Signs*

Organic Signs	Number of Cases
Hemiparesis or hemiplegia	7
Inequality of reflexes	6
Inequality of pupils	5
Ocular palsies	2
Sensory disturbances	8
Parkinson syndrome	1

ranging from one month to several months. That is, there was a period of well being after the accident, the patient returned to work and only after a period of time did incapacitating symptoms appear. All these patients had subjective complaints, all were litigation cases, and in all but two there was no history of unconsciousness. Table 2 shows the number of cases with and without unconsciousness and the duration when it was possible to determine it. This was not always easy in cases in which it was said to be momentary or to have lasted several minutes, but it probably is accurate. As will be seen, and this merely confirms the general experience, the number of patients who had prolonged unconsciousness, from one-half hour and longer, correlates very well with the number of cases of fracture of the skull, brain injury and concussion with encephalopathy. Also the number of cases with brief or no unconsciousness tallies with the number of those in which the diagnosis of hysteria or malingering was made. All patients with convulsions gave a history of prolonged unconsciousness after the accident.

Twenty-six patients showed major or minor evidence of organic involvement of the nervous system, in seventy-four the sequels were limited to mental symptoms. Tables 3 and 4 show the types of organic signs and sequels. In the one case in which a parkinsonian syndrome was found, the patient was overcome by smoke in addition to sustaining a fall and blow to the head which rendered him unconscious. An explanation

2. Parker, H. L., and Kernohan, J. W. The Relation of Injury and Glioma of the Brain. J. A. M. A. 97: 535-540 (Aug. 22) 1931.

3. As I am dealing with a group of 100 cases all figures refer both to the numbers and to the percentages.

for the apparent lack of correlation between the sequels and the organic signs may be found in the fact that some patients with no objective organic signs had such sequels as convulsions, conduct disorders or mental defects, while others with merely a few minor signs complained essentially of subjective disturbances. The latter, which will be discussed presently, refer to the symptoms which are generally classified as psychoneurotic, although in many instances they are based on definite pathologic changes of the brain.

The diagnoses (table 5) were based on a complete neurologic examination of every patient and on as thorough a psychiatric investigation as can be made in one or two hours. All patients had records of roentgen examination of the skull, a great many had records of lumbar punctures, a number had records of psychometric tests, and a few had reports of cephalographic studies. The one patient with traumatic psychosis was a man of 60, another patient who had a psychosis also had arteriosclerosis and the mental symptoms antedated the accident, hence the case was not diagnosed as traumatic psychosis.

Among the fourteen patients with fracture of the skull and brain injury were two who had meningeal hemorrhage, two had subdural hematomas and four had cerebral hemorrhage, that is, apoplectic rupture of an intracerebral vessel. There is no record in this series of patients with meningitis or abscess, for the good reason that I am dealing with chronic cases and not with acute brain injuries and because patients with those complications generally die. The patient whose only sign was loss of a sense of depth, of spatial orientation, very likely had a discrete hemorrhage into the left occipital lobe on the lateral side.

Although the single instance of traumatic psychosis in the series does not justify any conclusions, a few general remarks may not be out of place. The literature on the subject is neither very extensive nor convincing. Adolph Meyer⁴ wrote of mental disorders following trauma to the head many years ago, and quite recently Gordon⁵ made a study of the subject. The impression gained is that there is considerable latitude

itself to whether trauma to the head can cause a manic depressive state, a schizophrenia, a paranoia or a melancholia. This is doubtful, but if trauma may precipitate a psychosis, the injury need not necessarily be to the head. Whether head trauma can precipitate dementia paralytica, alcoholic insanity or a psychosis based on cerebral arteriosclerosis is quite another question.

The incidence of convulsions following trauma to the head presents another debatable question. The present series is entirely too small to permit of generalizations. The fact that it occurred in eight of 100 cases of all kinds and out of twenty-six patients with evident organic brain injury is of significance but still does not justify conclusions. As a matter of fact, there is

TABLE 5—Diagnoses

a wide divergence of opinion on the subject, and the results of statistical studies are so far apart that it is difficult to set up any criteria. Turner's⁶ figures are less than 5 per cent out of a total 18,000 cases of gunshot wounds of the head. The statistics of Muskens⁷ are difficult to evaluate and hence they are not reliable. Sargent's⁸ figures are not quite conclusive, Wagstaffe⁹ cites the incidence as only 2 per cent. Collier¹⁰ found an incidence of from 5 to 8 per cent, whereas Steinthal and Nagel¹¹ give an incidence of 29 per cent. Glaser and Shafer¹² cite sixteen cases and reckon the incidence at 6 per cent, but if one deducts the seven cases of hysterio-epilepsy, the percentage falls to 3.5. The point is that the cases studied are not comparable and the materials, no less than the observers, vary to such an extent that it is difficult to find a common basis for reckoning percentage incidence. One thing that all observers are agreed on is that there must be definite injury to the brain and that a time interval of not less than two months must elapse between the receipt of the injury and the onset of convulsions. Whether it is fair to stretch the interval to ten, fifteen and more years is a matter of opinion. Another debatable point is whether trauma to the head, not necessarily severe, can call forth convulsions in a "potential epileptic." The difficulty here is that no one can define the term potential epileptic patient.

CLINICAL CLASSIFICATION OF POST-TRAUMATIC SYNDROMES

If we do not consider the patients in this series who had objective signs of brain injury and those who gave definite evidence of brain damage or defect in the

in the use of the term traumatic insanity. It seems to me that such symptoms as delirium, excitement and disorientation, whether brief or prolonged, occurring in the acute course of skull fractures and brain injuries, cannot be included in the psychoses under discussion, any more than the acute delirium of typhoid, for example. Nor, properly speaking, should aphasia, or mental deterioration with memory defect, sometimes seen in children and less frequently in adults, be included, for the reason that we are dealing with brain defects and not true psychoses. It is a moot point, too, whether the deterioration in epileptic patients is secondary to the convulsions or the trauma. The question really reduces

nature of convulsions, mental deterioration or other signs and symptoms, there remains a group of individuals who, following a blow to the head, complain of subjective disturbances which are difficult to evaluate. They are practically the same in all cases, no matter what the underlying basis or explanation. They consist essentially of headache, dizziness and impairment of memory or lack of power of concentration and fears and anxieties, vasomotor disturbances, tremors, impairment of vision, inability to work and a host of other complaints. The dizziness in most of the cases does not represent an obvious vestibular reaction, certainly it is not the true vertigo which is accompanied by nystagmus, past-pointing, falling, or nausea and vomiting. The tremors and other objective signs are found on close examination not to be organically determined, while the impairment of memory is found to consist of lack of attention rather than of a true defect. It is important to emphasize that in the vast majority of the cases it is impossible from the description of the symptomatology alone to make a differential diagnosis. It is imperative, therefore, to seek other criteria and other diagnostic aids and, if possible, to arrive at some common understanding.

To add to the difficulties, many clinicians use different terms for the same condition or the same term for different conditions. One finds the diagnosis of traumatic hysteria and traumatic neurosis used interchangeably and indiscriminately, and the diagnosis of concussion is capriciously applied to clinical syndromes which neither from the history nor from the symptomatology can be differentiated from the other two. The term traumatic encephalopathy, though pathologically correct, has added somewhat to the general uncertainty, and so has the lack of use or the indiscriminate use of the encephalogram. Not that the term as well as the diagnostic method is not extremely valuable, but they need more specific definition and particularly more definite correlation with other facts. I would therefore, without introducing new concepts, submit the following classification of the syndromes in cases of head injuries in which the symptomatology is essentially psychic or mental. The criteria are based on theoretical and clinical considerations and on the analysis of cases as seen by the neurologist and psychiatrist.

1 *Malingering*—True and unalloyed malingering is probably the least important and certainly the least common of the syndromes following head injury. Out of the hundred cases under analysis there was but one with outright simulation and only two patients who, in addition to their hysterical symptoms, gave some evidence of malingering. The rarity of the condition accords more or less with general experience, and it is well known that malingering is more common with regard to the psychoses than the neuroses. The statement as to the comparative rarity of flagrant malingering must be qualified, however, by the observation that in practically all post-traumatic syndromes there is the tendency to overvaluation of symptoms, to preoccupation with symptoms, to exaggeration of complaints and to a desire to shift responsibility from oneself onto others. Even patients with definite signs of brain injury are apt to show psychogenic coloration of symptoms. Up to a certain point all this may be regarded as almost normal, particularly if one takes into account the ready suggestibility of most people. The individual becomes a malingerer only when he consciously and purposely, in order to deceive, to evade responsibility or to derive gain feigns illness and voluntarily tries to reproduce

signs and symptoms which he really does not have or extravagantly exaggerates minor ones which he has. This is not the place to enter into a discussion of the diagnostic criteria of malingering. The diagnosis, while generally not difficult to make, sometimes is extremely so and often taxes the ingenuity of the most expert. Suffice it to say that, whereas in the neurotic the symptoms are unconsciously determined, in the malingerer they are always conscious impostures. Nor can the histrionic simulation occasionally seen in hysterics be classified as malingering, although the hysterical patient can also be a malingerer. Malingering invariably occurs when the trauma is slight and the initial symptoms minimal.

2 *Traumatic Hysteria*—This is the most common sequel of head trauma that is not accompanied by gross evidence of organic brain injury. The diagnosis was made outright in thirty-seven of the cases under analysis, in two others there arose the question of simulation in addition to the hysteria, and in seventeen others, in which the history of unconsciousness also justified the diagnosis of concussion, there was a definite hysterical superimposition. Altogether, this sequel was present in 56 per cent of the entire series, and, if the seventy-four patients with subjective complaints alone are considered, the percentage mounts to 75.

The diagnosis of traumatic hysteria must be based on one set of negative and one set of positive criteria. Patients falling in this group give either no history of unconsciousness or only a history of very brief loss of consciousness, show no clinical signs of brain injury, no evidence of fracture on the x-ray plate, no history of subarachnoid bleeding in cases in which a spinal tap was done, and, in cases in which grave doubts as to diagnosis justify an encephalogram, no evidence of a cerebral pathologic condition. Merely negative evidence, however, is not sufficient, and the diagnosis cannot be made by exclusion alone. There must also be positive evidence that the trauma called forth psychogenic symptoms, that there is a hysterical reaction in an individual who has an underlying neurotic personality make-up. The patient makes unconscious use of the trauma to solve personality difficulties. The accident brings to a head a series of inner and outer conflicts which the patient was unable to face squarely or to solve adequately. The trauma precipitates the neurosis, sets in motion the same mental mechanisms as in any other hysteria and serves as a convenient solution of industrial, social, marital, familial or psychosexual conflicts. It should be emphasized that the individual is not consciously aware of the mental mechanisms, when he is, one is not dealing with hysteria. Nor must the litigation motif be paramount. Not that litigation and compensation do not play some rôle, but when they play the chief rôle or become the sole cause for the perpetuation of symptoms one comes dangerously close to malingering. The trauma may therefore be regarded as a definite precipitating and, in this sense only, as a causative factor. It is interesting to note that compulsion and obsessional neuroses are never, or rarely ever, precipitated by head trauma.

3 *Concussion or Traumatic Encephalopathy*—This occurs in a fairly large percentage of patients suffering trauma to the head. In eleven cases in the series the diagnosis of encephalopathy was made outright and in seventeen a diagnosis of concussion plus hysteria was made, that is, a total of 28 per cent. In every case there was a history of more or less prolonged unconsciousness. The symptoms were entirely subjective in

all of them and in but few more were there even minimal clinical signs of organic disease of the nervous system

There is an increasing tendency to speak of concussion of the brain in terms of traumatic encephalopathy, in fact, the two terms are beginning to be used interchangeably. There is no doubt that the old definition of a molecular disturbance does not hold any longer. The presence of minute hemorrhages, glial changes, cell and fiber degeneration, disturbed dynamics of the cerebrospinal fluid within the skull, ventricular distortion and brain atrophy justifies the designation of traumatic encephalopathy. Martland's¹³ work on brain changes in prize fighters threw great light on the subject. The investigations of Foerster and Penfield¹⁴ and of Bielschowsky¹⁵ also added to the knowledge. More recently Rand and Courville¹⁶ have studied the effect of head trauma on the fiber system of the brain. The encephalographic studies of head injuries by Friedman¹⁷ and others have shown the extent of ventricular and brain changes in patients whose main complaints were of a subjective nature. Kennedy¹⁸ has laid down a few excellent criteria for the appraisal of the effects of head injuries. Without citing further references to the literature it may be emphasized that concussion is not a simple process and that it consists of fairly definite pathologic changes consequent on trauma to the head, which is accompanied by unconsciousness at the time of the accident. The diagnosis of concussion or encephalopathy is beginning to depend, therefore, more and more on other criteria than on those furnished by the symptomatology. In itself this differs in no wise from that of traumatic hysteria. One must rely chiefly on the history of prolonged unconsciousness, on the presence of "small signs" of neurologic involvement, on the absence of psychogenic causal factors, on the persistence and severity of symptoms, and on the evidence furnished by the encephalogram when other facts are not sufficient to establish a positive diagnosis.

4 *Traumatic Neurosis*—This is, in my opinion, a comparatively uncommon condition. I made the diagnosis in but five of the hundred cases of head injury. The correctness of the statement as to its infrequency obviously depends on the acceptance of certain criteria for diagnosis. If traumatic neurosis and traumatic hysteria are used synonymously and interchangeably, the terminology is not only confusing but rests on sheer caprice, in which case one of the terms should be discarded. If, on the other hand, one is dealing with two distinct neurologic entities, as I believe to be the case, then it becomes incumbent to delimit them and, if possible, to adhere to a more strict definition of each term.

The clinical syndrome of traumatic neurosis differs little from that of hysteria but is not dependent, as far as one can tell, on the unconscious use of the accident to solve difficulties that have nothing to do with the trauma. That is, one is not dealing with a patient who had a neurotic personality to begin with. As far as possible the existence of concussion or traumatic

encephalopathy must also be excluded. This leaves a small group of previously well adjusted individuals, who, following a serious threat to life, in which there was comparatively mild or even trifling injury to the head, beget a stubborn set of symptoms which are not amenable to suggestive therapy or other forms of psychotherapy. Their condition bears resemblance to some of the war neuroses of soldiers who had been through particularly harrowing experiences, which they subsequently relived in their dreams. To use a psychoanalytic explanation, there is narcissistic regression, but the ego instincts rather than the psychosexual instincts are affected. Traumatic neurosis might possibly be grouped with the true or actual neuroses, in which neurasthenia, anxiety neurosis and hypochondriasis are included, but the intrapsychic conflict with regard to the ego or self-preservation instincts, which is assumed to exist in traumatic neurosis, would argue against its inclusion. Whatever the explanation, the fact remains that there is a small group of patients, without demonstrable cerebral pathologic changes, in whom hysterical mechanisms cannot be demonstrated, in whom compensation or litigation does not play a predominant role, who are resistive to treatment and who find it difficult or impossible to return to their occupation at which they sustained the accident. It is to this group that the diagnosis of traumatic neurosis may be correctly applied.

CONCLUSIONS

There are so many pitfalls in the proper evaluation of signs and symptoms following trauma to the head that it is often difficult to arrive at a conclusion or to express an opinion with definite assurance. This holds true to some extent in cases showing definite evidence of brain injury, but it is particularly true of those manifesting subjective syndromes. It is agreed that trauma to the head is fraught with grave possibilities and serious consequences and that prolonged unconsciousness, even in the absence of skull fracture or objective signs of brain injury, may be followed by incapacitating sequels lasting months and years. However, it may be stated that, with few exceptions, signs of injury to the nervous system set in immediately or within a few hours, more rarely a few days, after the accident. Mental symptoms, particularly headache and dizziness, may set in later, and convulsions may appear months or years after the receipt of head trauma. Generally, the longer the interval the more difficult it is to establish a causal relationship between trauma and its alleged sequels. In rare instances the already existing pathologic changes of dementia paralytica, alcoholism and the convulsive state may be aggravated by trauma, but they may also be responsible both for the accident and for the injury. Though very difficult, it is essential in all cases to determine the exact amount of brain injury and the degree of psychic coloration of symptoms that is present in most instances. In doubtful cases, but not as a general routine, encephalography is of great diagnostic help. As this procedure is always unpleasant and occasionally not without dangers, it should be resorted to only as a last measure and with due discrimination.

Clinically it is not easy to differentiate the subjective complaints which follow in the wake of the vast majority of cases of trauma to the head, and it is often impossible to state from the symptomatology alone what the nature of the syndrome is. Every case, therefore, requires not only special evaluation of signs and symptoms but also personality studies. In view of

the existing differences of opinion, of the lack of knowledge and agreement as to the nature of the underlying pathologic changes, and of the confusion in terminology, a tentative classification of post-traumatic syndromes is suggested and the criteria for their recognition are discussed. The syndromes are (1) malingering, (2) traumatic hysteria, (3) traumatic encephalopathy or concussion, and (4) traumatic neurosis.

1112 Park Avenue

ABSTRACT OF DISCUSSION

DR. N. W. WINKELMAN, Philadelphia. As has been shown malingering is not common, and even hysteria is not as common as customarily thought. In a study of a large series of cases histologically I have been surprised to find changes in the brain that were indisputable. In many of these, hysteria had been considered as a diagnosis. One is surprised to see in a group of post-traumatic cases a unanimity of complaints, as though the patients had rehearsed the symptom complex with one another. That is a statement which has been made for many years, that patients no matter how ignorant after head trauma complain of a group of symptoms that conform to the general group. That in itself is a remarkable thing. It is not only the trauma it is the immediate handling of the trauma case sometimes that produces the after-results. When one says that a trauma is mild and that the patient was unconscious for five or ten minutes, I don't believe one is giving the entire story. I should like to know what the treatment of that patient has been. Edema following even a mild concussion may provoke an anoxic condition in the brain similar to anoxemia from any cause. So it is not only the trauma but the handling of a patient afterward that determines what will happen to that brain, the most sensitive organ of the body, an organ that degenerates with a loss of blood supply in eight minutes and completely degenerates in less than fifteen minutes something that physicians are sometimes a little lax about remembering. I have found in a study of many trauma cases months and years after, indisputable evidence that trauma to the brain has produced a change—I would not use the term molecular—that can be recognized, a change that is capable of producing symptoms mental and neurologic. When clinical diagnoses keep pace with advances in the other phases of neurology, I believe that eventually neurologists will be able to pick out those cases which will show under the microscope changes that any one can recognize.

DR. GEORGE B. HASSIN, Chicago. Trauma is probably a more frequent cause of peripheral and central nerve disorders than such common factors as infection or intoxication. It should therefore be considered among possible causes of those individual pathologic conditions of the nervous system in which the etiology may be obscured by a forgotten injury. Falls, electrical shocks, blows, jarring of the body produced by sudden stoppage of a fast moving train or car and similar causes may bring forth a great variety of disorders of the nervous system conveniently classified as post-traumatic syndromes. One such classification has been offered by Dr. Wechsler. The majority of syndromes he mentioned used to be described as functional or as traumatic neuroses. At present, they are practically all organic. That is to say they show under the microscope demonstrable changes in the nervous system, excepting the classic cases of hysteria and malingering. I should add to these two conditions so called compensation hysteria, which however, like malingering is not a morbid entity. In compensation hysteria an individual worries over a possible unfavorable outcome of his claims, while a malingerer consciously tries to deceive the examiner by exaggerated and unjustified complaints. Another important group of post-traumatic syndromes comprises mental disorders. In the majority of cases it is not possible to establish an organic basis for so-called traumatic psychoses but with the perfection of the methods of neuropsychiatric research it will probably be possible to prove that even psychoses may be caused by trauma.

DR. TEMPLE FAY, Philadelphia. Dr. Wechsler has presented a valuable summary and classification of post-traumatic syn-

dromes. The problem of brain trauma involves a surgical principle concerning repair of damaged tissue. A wound, chronic ulcer or bed sore presents the same problem. The surgical principle underlying repair and maintenance of living tissue, brain or otherwise, demands that the maximum amount of circulation, nutrition and oxygen must be made available and maintained at all times. Following a cerebral commotion there is anemia, edema and pressure. Nature attempts to induce a hyperemia so as to assure oxygenization and nutrition to the injured part. Pressure rises as a result of the increase in blood volume, and compression anemia follows because the skull cannot expand to permit this congestion at one point without the sacrifice of necessary circulating blood volume in another. The cranial total volume remains fixed. The addition of a new factor means the equal subtraction of another. The brain is an organ that happens to have a more complex expression of symptoms but, nevertheless, it is dependent on adequate oxygen and nutrition for its survival. One cannot get blood, oxygen and nutrition back into the cranial cavity unless one makes room for it. Decompression, spinal drainage and dehydration permit additional space temporarily for the return of a nutritional blood supply necessary to maintain the function of the organ and prevent the final symptoms of anemia and softening. In the last ten years, 837 cases of head injury have come under my observation. I attempt to maintain the initial surgical principle by continued dehydration so as to promote the maximum circulation to the brain at all times at the expense of the less important elements, primarily spinal fluid volume. I have found that many of the post-traumatic syndromes described appear and disappear as the tide of the blood (nutrition and oxygen) rises and falls. After spinal drainage (or an encephalogram), and continued fluid and dietary limitation, these patients are definitely improved. Ninety-two per cent of a recent series on this program have been free from post-traumatic symptoms and able to return to work in three months. In the last analysis the function of the brain as an organ depends on adequate nutrition, and many of these vague post-traumatic symptoms are due to a chronic cerebral anemia. I am convinced that these symptoms may be prevented or controlled if measures are employed to maintain an adequate blood supply during and after the phase of the injury. I have found that careful and continued "dehydration" is required to obtain this end.

DR. J. L. FETTERMAN, Cleveland. Practically all modern writers on the subject are in accord with the author and with Drs. Hassin and Winkelman, that an organic basis underlies the emotional symptoms following head injury. However, there are some dissenting views. Reichardt, for example, disagrees. In a thesis that most of the neuroses following trauma are conditioned by the factor of compensation, Reichardt includes even many who have suffered cranial injury. He excludes cases of severe cerebral trauma such as intracranial hemorrhage, contusion of the brain and subdural hematoma. He believes that the remainder, many of the concussion cases, are influenced in their emotional symptoms by the factor of insurance. He cites the experience that among the uninsured and in the preinsurance era patients who suffered concussion of the brain cleared up in a remarkably faster time than do those who are insured. Dr. Wechsler did not emphasize underlying motives as responsible for neuroses after trauma to regions other than the cranium. In the traumatic neuroses of industry, for example, there are patients whose symptoms can be interpreted only as an escape from duties that are disagreeable, dangerous or as revenge against an employer. This constitutes an occupational type. In civil life one encounters patients whose neuroses in their onset development or disappearance reflect a claim for compensation. This is an indemnity type. In my experience the attitude to industry or toward compensation may be the dominating factor behind the symptoms of the neurosis. With reference to head trauma in children, Beekman wrote that post-traumatic sequelae were decidedly less common than among adults. Does Dr. Wechsler explain this difference on an anatomic basis or does he subscribe to the view of Davis, who discussed Beekman's paper? Davis suggested that it wasn't so much a physical difference as a psychic one. Children are less subject to social and economic motives, less influenced by "gain from illness" than adults.

DR. GEORGE W. HALL, Chicago I have been interested in this subject for a long time. How many persons have not been knocked unconscious at one time or another? The difficulty in evaluating cases of trauma to the central nervous system is that these tabulations as expressed by the author come from a specialist who has seen only the severe cases after they have been milled over, so to speak, by other physicians. Consequently many cases escape his notice entirely, even though the patient may have been rendered unconscious at some time. It is difficult to arrive at the proper conclusions from a statistical standpoint on which any classification can be made. There is no doubt in my mind that, as Dr. Wechsler says, in many cases the desire to escape from the difficulties of life is an important factor, if one can study these cases as they come. Another point I would like to make is that recently there has been entirely too much stress placed on the possible changes shown in an encephalogram. I know of a clinic in this country that desires to make encephalograms in every case of brain injury or injury to the skull, which of course I think is a mistake. The relative importance of an encephalogram is not known as yet. There are very few men in this country who can read an encephalogram with the proper degree of accuracy. Consequently in my opinion the importance of an encephalogram is too strongly emphasized. It brings about the old statement that one should not allow the laboratory to make the diagnosis. Another point brought out by one of the discussers is that children do not suffer the after-effects of these injuries simply because (and this is based on Dr. Wechsler's statement) the child desires to go on and play; he does not want to quit, and consequently he makes a very good recovery, whereas the individual becomes, of course, more profoundly neurotic after the injury if there was a predisposition to neurosis. There can be no question that there is a connection sometimes between brain injury, especially a basal skull fracture, and the possibility of developing other diseases. Not so long ago I had the privilege of seeing a case of basal skull fracture in which meningitis developed within a period of three or four days. The meningococci were found and the serum was used. The patient made a complete recovery. I think that Dr. Wechsler's classification is a good one and his percentage is very encouraging, in view of the fact that he sees these cases after the average practicing physician has not been able to solve the problem.

DR. WALTER FREEMAN, Washington, D. C. There is a tendency in some locations, Washington for one, toward a great increase in the number of claimed disabilities under workmen's compensation acts, and there has been a tendency on the part of some physicians to claim that the neurosis itself, in the absence of a traumatic encephalopathy, is a disabling disease. It seems to me that this is a very radical view and I should like to have Dr. Wechsler's reaction to it.

DR. MAX H. WEINBERG, Pittsburgh I agree with Dr. Wechsler. It is unfair to discuss his paper more or less critically, because he could not give his paper in its entirety. This is one of the saddest and most pressing problems that neurologists have to put up with. Opinions differ sharply about these patients, but is it a mistake to give them so much attention? The question Dr. Winkelman raised especially is interesting. It is significant how some of the most ignorant people give definite symptoms, as though they had read the books on the subject. There must be some reason for patients complaining of the same symptoms, such as dizziness, especially on bending, severe headache, with exacerbations and loss of memory. It is this group that is most disputed. What are neurologists going to do about these cases? It is all well enough to postulate that as soon as the litigation is over everything is going to be lovely with the patient, but this is found not to be so. The dehydration treatment, in accordance with principles laid down by Dr. Fay, is particularly valuable in this type of case and prevents many such sequelae. Dr. Wechsler rightfully stressed that the results do not depend so much on the extent of injury or the amount of the force but that it is a question of what happens to the brain and, as it seems, a great deal does happen. There is no doubt, however, that the question of personal equation does come in, for one has dropped the term 'traumatic neurosis' altogether in the last three years. I refer to these cases, once they present this group of symptoms as head injury syndromes.

With careful scrutiny, one will always find some organic cerebral changes. I therefore wish to emphasize that these head injuries are very serious as far as efficiency is concerned. I should like to ask the program committee in the future, when arranging for this kind of paper, to make an exception in the case of the original discussor and extend his time so that all of us can arrive at a fairly definite conclusion about these cases.

DR. C. C. NASH, Dallas, Texas There is one question I should like to ask as a neurologic surgeon and not as a neuropsychiatrist. In testifying in court, how is one going to differentiate between traumatic hysteria and malingering? It is one thing for a medical organization to say that a man is a malingerer but to get on the witness stand and say that this man is a malingerer and that there is nothing the matter with him, as I have learned from sad experience, is something one had better not do unless one is absolutely sure of oneself. Recently I had a court experience in which a man claimed to be paralyzed from a stroke of apoplexy resulting from sunstroke. His left leg and left arm were supposed to be paralyzed, and he walked in on a pair of crutches dragging his foot. He walked on his crutches, supported his weight and had corns on the bases of his hands. The attorney asked me if I would say this man was a malingerer. I said, 'No. I couldn't find anything the matter with him, that was all.' Needless to say, the jury didn't believe me. They gave him total disability. The compensation laws in Texas provide that the man must be able to be returned to the same or similar occupation in which he was engaged at the time of the injury. He might be the finest stenographer in the world and be able to do that kind of work, but if he worked as a day laborer at the time of his injury he has to be paid total disability if he cannot return to that kind of work.

DR. E. E. MAYER, Pittsburgh As well as Dr. Wechsler could be followed in the incomplete reading of his paper, I gather that he is dealing only with residual syndromes. Most of the discussion seems to me, therefore, inappropriate in that acute and chronic cases are not separated. My experience is that the acute syndromes directly following head trauma differ from the chronic forms. I cannot find in hysteria that is connected with head trauma anything that differs from hysteria without head trauma. I cannot reconcile myself, therefore, to Dr. Winkelman's argument that cases of hysteria present brain changes, even if no clinical symptoms of an organic nature are present. Wherein does the distinction lie between hysteria without concussion and hysteria with concussion? The unrehearsed likeness of the complaints is not a proof of a common pathologic background but only a proof of a similarity in human nature in its mental mechanisms. Hysterical symptoms are compromises serving to conceal the real sources of a psychic conflict whether they occur with trauma or without trauma of a physical kind. The seeming uniformity of the psychology of the neuroses in the traumatic group is, however, more apparent than real, and it is still necessary to study individual differences. There is a group in which organic injury occurs and yet is mistakenly considered to belong to the traumatic neuroses. Mild as well as fugitive and transitory disorders of taxis and praxis must persistently be looked for and often will be found if patients are under continuous scrutiny. A transitory diplopia, a fragmentary amnesia or an actual thalamic type of pain is not uncommon. Particularly with the patient who has vertigo and who is not neurotic, or the patient who complains of petit mal seizures, will a thorough study often reveal that the post-traumatic state is on an organic basis. And I need hardly remind this group that the pathologic condition is sometimes found to be on an arteriosclerotic basis and not actually but only seemingly through close association, a post-traumatic one. Classifications are largely personal, and if Dr. Wechsler gets satisfaction in his clinical work from the four-phase classification he has given it need not follow that it would serve as satisfactorily for others. Neurologists still differ too much in the meaning of their cases, largely because of incomplete grasp of basic physiologic principles in connection with the brain, to classify one from the other.

DR. I. S. WECHSLER, New York While I agree with Drs. Winkelman, Hassin and Fay about the pathologic changes in certain types of brain injuries, I am more concerned with the group the symptomatology of which is so uniform and the

classification so difficult. The very profusion of terms used by the discussers bespeaks our confusion. We speak of compensation neuroses, litigation neuroses, hysterical neuroses, traumatic neuroses, traumatic neurasthenia, concussion, encephalography, ego neuroses, malingering, and what not. The question is, 'Are the criteria I suggested acceptable?' It is facetiously said that, when a brick falls on a man's head, the first question he asks on coming to is not what happened to his head but to whom the brick belongs. None the less I feel that outright malingering is not very common provided one adheres to a very strict definition. Compensation or litigation as the predominating motive comes very close to the malingering. In the second or traumatic hysteria group the patients utilize trauma as an unconscious excuse for the solution of personal problems. Hence the need of personality studies. In the traumatic neurosis group one deals with a different personality with a different ego reaction albeit an identical symptomatology. Finally there is the group of patients who undoubtedly have brain changes, however minute. I agree with Dr Hall that the encephalogram should not be used indiscriminately. It is not always harmless and it always is unpleasant. The word 'concussion' will have to be redefined or discarded when more is known about encephalopathy, it may be used as a substitute. The point is to agree on definitions and classifications, however tentative. As to trauma in children, I find that children either do very badly or very well. They recover better than adults or show more residual defects, especially retardations. To answer Dr Nash, I agree that if a patient utilizes compensation and litigation to perpetuate the neurosis he is malingering. As the study refers to post-traumatic conditions, I purposely left out acute injuries. May I reiterate that in my experience traumatic psychosis is extremely rare. What I have in mind is a true post-traumatic organic psychosis due to actual injury of the brain and not an emotional or other psychosis precipitated by trauma.

INFECTIONS BY GAS-FORMING ANAEROBIC BACILLI

AN ANALYSIS

JAMES R. REEVES, MD

Resident in Pathology, Indiana University School of Medicine
INDIANAPOLIS

The present state of our knowledge concerning infections caused by anaerobic gas-forming bacilli is one of confusion. This is no doubt due to the fact that any lesion characterized by the presence of gas in the tissues, together with large gram-positive bacilli, is considered to be gas gangrene. Apparently in most cases neither the history of the infection, the clinical course nor the kind of gram-positive bacteria present alters the diagnosis. The great number of unsound tests that are still being used to determine the presence of *Clostridium Welchii* (the Welch bacillus) is another factor that does little to aid in clarifying the present situation.

All bacilli that grow in the absence of oxygen and form spores are grouped in the genus *Clostridium*, of which at present about 100 members are classified. Nearly all these organisms form gas in certain situations, but this is not a great factor in their classification, since the aerobic colon group and the streptococci also form gas and frequently do so in infected tissue. Of the 100 species of anaerobic spore-forming bacilli, seventeen are pathogenic for some form of animal life, whereas only seven are in the true sense pathogenic for man. Of these seven, *Clostridium tetani* is probably most important. It is the cause of tetanus and is familiar to all. *Clostridium botulinum* the agent responsible for food poisoning, since the advent of adequate methods of processing of canned foods, is no

longer an urgent problem and seldom is encountered. The remaining five species of pathogenic organisms constitute the group that is responsible for malignant wound infections attended by edema, necrosis, toxemia and collections of gas, such as were seen so frequently during the World War.

Clostridium Welchii is the most important member of this group of five organisms. At present it has eleven synonyms, the most frequently used of which are *Bacillus perfringens*, *B. Welchii* and the gas bacillus. This organism is a short, thick, capsule-bearing rod with truncated ends (square, with rounded corners), which produces a filtrate of highly varying toxicity and hemolytic action. It was found as the only organism in 14 per cent of gas gangrene in war wounds. Together with other anaerobes it was found in 65 per cent. This shows that it played the major role, i. e., 79 per cent, in causing the emphysematous or most virulent type of gas gangrene in the World War. The next most frequent invader and probably second to *Clostridium Welchii* in toxicity is *Vibrio septique*. There is still some uncertainty about the correct name for this organism. Bergey's classification considers *Vibrio septique* of Pasteur to be identical with the bacillus of malignant edema of Koch. The Standard Classified Nomenclature of Disease refers to them as different organisms and gives *Clostridium septicum* (*Vibrio septique*) as the cause of malignant edema. Bacteriologists, I think, will continue to consider *Clostridium oedematiens*-maligni as identical with both organisms of the Franco-German argument and ascribe to it the cause of malignant edema. The remaining three organisms, namely, *Clostridium oedematiens* (*B. novyi*), *Clostridium histolyticum* and less frequently *Clostridium fallax* are not often found and their identification is of no great importance to the clinician.

Gas gangrene is a clinical entity first described by Maisonneuve in 1853. During the Crimean War (1854-1856) the first series of cases was collected. Little was known of the etiology until Welch in 1893 described the organism that causes it. The typical picture of true *Clostridium Welchii* infection varies in severity with the portal of entry and the virulence of the infecting organism. In the cases of puerperal sepsis reported by Toombs and Michelson,¹ the mortality rate was 95 per cent. They were fulminating infections characterized by jaundice in more than 50 per cent of the cases, marked leukocytosis, usually from 25,000 to 90,000, rapidly developing secondary anemia, low hemoglobin and high fever. About 50 per cent of these patients were dead in forty-eight hours, only a small percentage living past the fifth day. True *Clostridium Welchii* infections of the extremities give a similar but somewhat milder clinical picture. The death rate during the war was about 50 per cent, whereas the series of cases from medical literature that I studied and that occurred during civil life showed a death rate much higher.

The toxicity of various strains of the four types of *Clostridium Welchii* is variable, testing sometimes as low as 1. In this laboratory, efforts to verify the reports that there are nontoxic strains of this organism have been unsuccessful. All strains studied here that fulfilled the growth characteristics of *Clostridium Welchii* produced a filtrate that was hemolytic and toxic,

¹ Toombs P. W. and Michelson I. D. *Clostridium Welchii* Septicemia Complicating Prolonged Labor Due to Obstructing Myoma of the Uterus. *Am. J. Obst. & Gynec.* 15: 379 (March) 1928.

usually to a high degree, testing from 1 to 4 to 1 to 7² when fresh animal serum was added to the medium. Toxins were made by inoculating tubes of veal meat infusion medium, to which fresh animal serum had been added up to 10 per cent. The culture was passed through a Berkefeld candle after forty-eight hours, and the resulting filtrate was tested as described.

Medical literature, particularly in the last twenty years, contains many reports giving *Clostridium Welchii* as the etiologic agent in a wide variation of clinical conditions. Torrey and Kahn,³ on the basis of experimental anemia in rabbits, produced by intramarrow injections of *Clostridium Welchii* toxin, claimed some similarity to primary pernicious anemia in man. Gordon-Taylor and Whitby,⁴ after a study of fifty cases, concluded that *Clostridium Welchii* is usually associated with acute cholecystitis. They also found the organism in 13 per cent of all gallstones removed at operation. Jennings⁵ finds *Clostridium Welchii* in the lumen of the appendix in 90 per cent of cases. *Clostridium Welchii* was reported by several to cause the toxemia of intestinal obstruction. Most of the foregoing work has been disproved. Many of the single case reports are not reliable. Of the cases that I reviewed, about one third were probably not true *Clostridium Welchii* infections. Cramp⁶ in 1912 reviewed 187 cases occurring up to that time, including twenty-five of his own. Of these 187 cases, approximately 30 per cent, in the light of more recent knowledge, were not *Clostridium Welchii* infections.

The most recent attempt to establish *Clostridium Welchii* as the cause of a different pathologic state is that of Andrews, Rewbridge and Hrdina.⁷ These workers assert that the Welch bacillus is a normal inhabitant of the liver and muscles of normal healthy dogs and, in severe irritations of the peritoneum by sterile autolyzed liver suspensions or 10 per cent bile salt solutions, will migrate out, causing a bacterial peritonitis and death from B. Welchii toxemia. In 1931 Trusler and Reeves⁸ reported on the bacterial flora of the livers and muscles of normal dogs. Since 1931 the complete work of Andrews and his associates has been repeated in our laboratory and an extensive study of the problem made by means of a more strict bacteriologic technic. A report of this experimental work has been accepted for publication by the *Archives of Surgery*. We were unable to duplicate the results of the foregoing experimenters but found that while the tissues, notably liver, spleen and muscles, of apparently normal healthy dogs regularly contained bacteria, *Clostridium Welchii* was not found to be present. Ordinary surgical cleanliness is not sufficiently accurate for the needs of this work and we believe that the results obtained by previous workers were due to contamination in the collection of the sample to be cultured or to incomplete cultural study of the organisms found.

² A test of 1 to 7 means that 1 cc. of the filtrate diluted to a total volume of 7 cc. with physiologic solution of sodium chloride will, when 1 cc. of the diluted suspension is injected intramuscularly, kill a 250 Gm. pigeon within twenty-four hours.

Most of the experimental evidence and clinical conclusions linking *Clostridium Welchii* with conditions other than true gas gangrene have been based on unsound tests for the presence of this organism. The work of Jennings and as recently as June and July 1934 cases reported by Orr,⁹ are based on finding *Clostridium Welchii* by inoculating a rabbit intravenously with suspected material and then incubating it, after killing it by a blow on the head. Large gram-positive organisms were then recovered from the tissues of the rabbit. The same or a similar result may be obtained by killing and incubating a rabbit without inoculation. In 1927 Nerb¹⁰ described a test whereby the presence of *Clostridium Welchii* could be detected as follows: Into the liver of a guinea-pig, 2 cc. of suspected material was injected, care being taken to traumatize the liver somewhat in the process. The animal was then killed by a blow on the head and incubated. If, after three hours of incubation, large gram-positive gas-forming bacilli were found in the peritoneal fluid, B. Welchii was considered to be present. Unfortunately, if 2 cc. of sterile saline solution is injected into the liver of a guinea-pig in the same manner, large gram-positive gas-forming bacilli are usually found in the peritoneal cavity after three hours' incubation. Both procedures described are obviously worthless and misleading. A great number of cases reported are based on direct smear which, in view of the morphologic similarity of these organisms, is utterly unreliable. Probably the most reliable single laboratory procedure is a capsule stain, since *Clostridium Welchii* is the only pathogenic anaerobic organism bearing a capsule. In our experience, reliable capsule stains are extremely difficult to make and this method of identification should be used only as an emergency measure and by technicians with considerable experience. Certainly before a case is reported or recorded in experimental work, strict anaerobic technic is necessary for positive identification.

If it is true that approximately one third of the infections reported as being due to *Clostridium Welchii* were incorrectly diagnosed as to etiology, the interesting question arises: What is the real cause of such infections? In this connection a review of various series of cases reported as being gas gangrene shows that they are divided about equally among the following causes:

1 Those cases following compound fractures with attendant contamination from soil or street dirt.

2 Those due to gunshot wounds and crushing wounds of the extremities, wherein muscle is injured and contaminated by dirt or dirty clothing.

3 Spontaneous gas infections without a history of contamination, arising after clean surgery and the parenteral administration of drugs and solutions.

Not included in this division are the cases of puerperal sepsis caused by *Clostridium Welchii* that are due to attempts at criminal abortion or instrumentation, of which some 300 have been reported and doubtless many others unrecognized.

As previously mentioned, about 30 per cent of the 187 cases reported by Cramp would fall in group 3. Orr's cases referred to before were seven in number, four of the patients were over 50 years of age, two of the four had circulatory failure, and one had diabetes.

¹⁰ Nerb, Louis. A Method of Prompt Identification of Bacillus Aerogenes-Capsulatus (B. Welchii). *S. Clin. North America* 7: 1021 (Aug.) 1927.

Case 17042¹¹ from the Massachusetts General Hospital is a good example of group 3. Foreign literature especially contains numerous cases that fall in the third group. In 1931 a committee at the New York Hospital for Bone and Joint Diseases,¹² appointed to determine why gas infections appeared so frequently in amputation stumps after clean surgery, brought forth some interesting facts. The committee considered that all the gas infections were caused by *Clostridium Welchii* and then discovered that most of the infections appeared in arteriosclerotic individuals or patients past the age of 50, some of whom had thrombo-angitis obliterans. These infections were mild, and recovery was the rule when the patients were in fairly good physical condition. As stated before, all series of cases, except war wounds, that I studied contain approximately one third that arise in patients past 50 years of age, in diabetic patients, in arteriosclerotic patients, and in patients with thrombo-angitis obliterans or generalized circulatory failure. These infections may be spontaneous, follow amputations for dry or moist gangrene, and appear after the parenteral injection of drugs and solutions and after bruises in which the skin is not broken. The clinical picture, as compared with true *Clostridium Welchii* infections, is relatively mild, the temperature from 100 to 102 F., white blood cells from 10,000 to 15,000, no jaundice, and no hemolysis or secondary anemia. The infected part gives off a foul odor and contains foul smelling gas, the muscles are blackened or reduced to a thick black paste, the skin is bronzed or purple, and the hair does not pull out. The line of demarcation is usually prominent. In true *Clostridium Welchii* gas gangrene there is nearly always a history of trauma with contamination, it occurs in all ages, severe pain occurs at the site of the infections and the temperature rises rapidly to 103 or 104. The white blood count ranges from 25,000 to 90,000, red blood cells may fall to 1,000,000 in twenty-four hours as the result of hemolysis, and some degree of secondary anemia is always present. Jaundice or a greenish pallor is present in more than 50 per cent of the cases. The patient perspires freely and is very toxic. The infected area is indurated and crepitant, the skin is often reddened but not otherwise discolored, the hair pulls out easily, the infected muscles are red, the wound exudes a red, hemolyzed serum and a gas, which does not have a putrefactive odor. Lines of demarcation are not prominent since the gas infiltrates along the muscular planes at some distance from the site of infection.

I have recently seen the case of a boy who fell from a cherry tree and suffered a compound fracture of the humerus at the elbow joint, the proximal fragment being thrust into the soil. Open reduction was done and the wound closed tightly. Thirty-six hours later the muscles around the elbow were crepitant and forty-eight hours later the boy was extremely jaundiced and had a temperature of 104. *Clostridium Welchii* was recovered, with other organisms, from the wound and in apparently pure culture from the blood stream. Recovery followed amputation below the shoulder and the administration of 100,000 units of *Clostridium Welchii* antitoxin. Fortunately for the patient, the organism recovered was only mildly toxic, testing 1 to 2 in our hands.

The various pathogenic organisms that cause true gas gangrene are distinct species, belonging mostly to the sacrolytic group, they are similar in morphology to one another and to numerous species of putrefactive proteolytic bacilli, only a few of which have so far been classified. There are myriads of these putrefactive, gas-forming, anaerobic bacilli lying dormant in the soil, periodically growing on bits of decaying organic matter and thereby maintaining their numbers. These organisms constantly contaminate food and it has been shown experimentally that they utilize the tissues and organs of animals to continue their existence. Evidence has been and still is being accumulated in this laboratory to show that in the latter decades of a human existence the organs and muscles may become contaminated by these saprophytes and that under certain conditions they can begin the destruction of the tissues before death. We believe that the type of putrefactive gas gangrene appearing mysteriously in older people, and those suffering from diabetes, arteriosclerosis and circulatory failure, is caused by these saprophytic bacteria already present in the tissue injured or deprived of its blood supply. All that is necessary for their growth is death of tissue. In dogs known to harbor similar organisms in their tissues, putrefactive gaseous lesions may be produced by trauma to muscles or the injection of toxic substances. These infections readily respond to adequate drainage, resection of the dead muscle, and supportive care.

In human subjects, treatment should be directed toward improvement of circulation, control of diabetes and removal of dead muscle. Certainly radical amputations are not warranted and specific *Clostridium Welchii* antitoxin is useless. In true *Clostridium Welchii* gas gangrene, antitoxin seems to be most valuable as a prophylactic agent. When the infection is established, it becomes a therapeutic aid second only in value to its early prophylactic use and debridement.

SUMMARY

1 Approximately 30 per cent of cases reported and treated as *Clostridium Welchii* gas gangrene are caused by other anaerobic organisms.

2 This 30 per cent of cases should be classed as putrefactive gangrene and treated conservatively by systemic supportive treatment, debridement and irrigations. *Clostridium Welchii* antitoxin is not indicated and may be injurious.

3 Putrefactive gangrene is likely to appear in patients past the age of 50 years who are constitutionally below normal. Cases appear notably in patients with circulatory failure, arteriosclerosis, thrombo-angitis obliterans and diabetes mellitus.

4 The direct cause for putrefactive gaseous lesions in the muscles of patients whose condition has been described may be bruises, burns, simple fractures, parenteral administration of drugs and solutions, and circulatory failure.

5 Putrefactive gas-forming anaerobic soil bacteria contaminate food at all times. It seems apparent that bacteria of this type are frequently present in the organs and muscles of the aged individual.

6 Diagnosis of *Clostridium Welchii* infection cannot be based on direct smear, the rabbit inoculation test or Nerb's test.

7 Diagnosis, for clinical purposes, of the presence of *Clostridium Welchii* can be made in experienced hands by capsule stains. However the only positive

identification is by the use of anaerobic cultural methods and related criteria

8 Patients suffering from wounds, particularly of muscle tissue, which have been contaminated with soil or street dirt, should be given gas gangrene antitoxin prophylactically and in addition should receive debridement and irrigations. If toxic symptoms develop, radical debridement, continuous irrigations and therapeutic serum are indicated without delay

FROST-BITES AMONG EMPLOYEES OF THE CITY OF NEW YORK

DURING THE WINTER OF 1933-1934

LEOPOLD BRAHDY, M.D.

NEW YORK

Among the regular and temporary employees of the Department of Sanitation, there were 388 cases of frost-bite between December 1933 and March 1934. One hundred and twenty-eight cases were mild, the men lost no time from work and required but one treatment. The data on these 128 cases were not available for inclusion in this study, which is limited to the 260 remaining cases.

One hundred and eighteen men had frost-bitten ears, of which four resulted in disfiguring scars, one had a frost-bitten nose, which left no noticeable scar, 113 had frost-bitten hands and fingers, twenty of whom have permanent defects varying from limitation of motion in one finger to almost complete loss of use of the hand. Of forty-two frost-bites of the feet there are four with similar variations of permanent defects. The classification of permanent defect does not include patients who complained of recurrent swelling of the affected part, tingling and sensitiveness to cold common complaints even among those who lost no time from work.

When an investigation into this condition was begun, it was supposed that the predisposing factors to injury by cold were high humidity, insufficient clothing, a long period of unemployment preceding the job as snow shoveler, previous indoor occupations, repeated freezing, age, physical fitness, preexisting disease and alcoholism. It was believed that slow thawing of the affected parts and early treatment might have avoided some of the poor end results. The data obtained indicated that these assumptions required modification.

The accompanying charts¹ show weather conditions in New York City from December 15 to March 15, the number of employees exposed and the number of frost-bite cases. The temperature and the wind velocity and the humidity on the graphs is the average of the first four hours of the usual working day. This period was taken because 75 per cent of the patients had symptoms after working four hours or less, 90 per cent had symptoms before the end of the working day, and the remaining 10 per cent did not have any symptoms except mild numbness till after they had gone home.

The single continuous line indicates the amount of snow on the ground in Central Park. On the city streets the snow remains much longer. A fair index of the amount of snow on the streets is the number of temporary snow shovelers employed. The double line indicates the total number of men employed in the

sanitation department. There are 14,000 regular employees, additional temporary employees for snow removal increased the number as shown on chart 1 to a maximum of 54,000.

Chart 1 shows that frost-bite occurred on January 29 although there was little snow removal going on. The seasoned worker is susceptible and the presence of snow is not the important factor. On the days when snow was falling (indicated by rise in cumulative snowfall) there were fewer frost-bites than one might expect from the temperature and wind.

On chart 2 the ratio of the number of frost-bites to 10,000 men exposed is shown. This brings out more clearly that at temperatures below 8 F, regardless of other conditions, an incidence of five or more frost-bites may be expected (chart 2, December 29, 30, February 8, 9, 10). When the temperature is between 8 and 14, the incidence of frost-bite is high only when there is a strong wind movement, the temperature may fall as low as 8 without causing many frost-bites (February 17). When the temperature reaches 24 frost-bites rarely occur, no matter how strong the wind.

On the days when a large number of frost-bites occur, the humidity was never high (maximum 60 on February 20, chart 2). There appears to be no close relationship between frost-bite and humidity.

The significance of wind is seen on comparing December 29 and 30. On these two days the temperature was about the same, on the 29th the wind movement was 13 miles per hour and on the 30th it dropped to 5 miles per hour. There was a sharp decrease in the incidence of frost-bite. On January 29 and February 3 and 10 the average temperature was the same (8 F) but on January 29 the wind movement was the highest of the winter (24 miles), while on February 3 it was 10 miles and on February 10 it was 14 miles per hour. The incidence of frost-bite on the windy day was nearly 8 for each 10,000 men exposed, while on the other two days it was less than 1. The humidity was about equal on the three days.

Most of these men were treated at the Department of Sanitation Clinic. The unexpected rush of cases did not permit general physical examination till some weeks after the onset, when all the milder cases had been closed. Among those with serious loss of part of the hands or feet, one had diabetes, one epilepsy, two myocarditis with circulatory insufficiency, one syphilitic endarteritis and one advanced arteriosclerosis. Moderate arteriosclerosis was not more frequent than usual in a similar group of laborers. Malnutrition evident on physical examination was found in two. All eight men, with underlying systemic conditions, were temporary employees.

RESULTS OF OBSERVATIONS

Duration and Repeated Exposure—A history of the symptoms of frost-bite in the affected part, either within a few days or in previous winters, was rarely obtained. Repeated freezing was not a factor in these cases. MacCallum² states that repeated exposure for short periods does not produce necrosis but, instead, hyperplasia with giant cell formation in the epidermis. This condition was not observed in any of our cases.

Workers who continued several hours after the first feeling of numbness had the worst frost-bites. The length of exposure after the first symptoms develop is more important than any other single factor.

From the Division of Workmen's Compensation Office of the Corporation Counsel of the City of New York.

¹ The graphs of weather conditions are based on the data in the Report of the New York Meteorological Observatory James H. Scarr, director, United States Weather Bureau.

² MacCallum W. G. Text Book of Pathology ed 5 Philadelphia W. B. Saunders Company 1932 p 363

Thawing—One patient with freezing feet went into a hot boiler room to get warm. He eventually lost two toes of his foot. This case, coming early in the series, gave us the impression that slow thawing was of the utmost importance. More careful investigation did not confirm this generally accepted idea. Many men with apparently severe frost-bites went into warm rooms without bad effect. In a large percentage of the serious cases the men were careful not to warm the freezing part rapidly, often going to extremes of caution in increasing the temperature slowly. A number of men rubbed the affected part with snow.

Age—All patients with serious underlying disease were over 45. Omitting these eight, the average age of men with serious frost-bites was but one year above the average of the group.

Chart 1—Temperature number of men employed in the department of sanitation cumulative snowfall on the ground in Central Park and the number of frost bites

Clothing—With few exceptions, none of the patients gave a history of feeling cold in the body. Temporary employees in some cases wore clothing that was too heavy for working with comfort. They felt warm after shoveling an hour and rested a while. It seems possible that the rest period, though the body was warm permits freezing of the extremities. Wet hands and feet occurred but not with sufficient frequency to be considered an important factor. One patient, with serious malnutrition, stated that he wore thin, old gloves. Such a history was unusual, most workers stating that their gloves gave as much protection as could be expected. The men do not seem to realize the need of woolen mittens. A common custom among workers is noteworthy. Many of them wore two pairs of socks or two pairs of gloves. This must result in some constriction of the feet and fingers and predisposes to frost-bite. With few exceptions, patients stated that they wore good shoes, but some wore shoes with soles too thin for this type of work.

Alcoholism—Direct questioning of individuals who had suffered from frost-bite would be unreliable on this subject and was done only when it seemed that the physician had their full confidence. From discussions with employees who did not sustain frost-bite, I had the impression that the consumption of alcohol during the working period and lunch time was very uncommon and not a factor in predisposing to frost-bite.

Coffee and Tobacco—The drinking of hot coffee in the course of the work and immediately after the end of work was common. When an employee went into a lunch room solely to warm up, he usually ordered a cup of coffee. Most men smoked as soon as they could get indoors.

The skin temperature of the fingers, toes and ears is lower than that of the body. It has been demonstrated

that caffeine³ and tobacco⁴ depress the temperature of the peripheral parts. Hot water, alcohol and acetylsalicylic acid, on the other hand, raise the peripheral temperature. Two cups of coffee (in a habitual coffee drinker) will lower the temperature of the fingers 2 degrees for several hours. A glass of hot water or 5 grains (0.3 Gm.) of acetylsalicylic acid will raise the peripheral temperature. The relation of tobacco and coffee to frost-bite deserves further investigation.

Nutrition—Undernourishment to a degree to be manifest on physical examination was

found in but two cases. Several temporary employees gave a history of daily food intake below normal in quality and quantity. Poor nutrition, even though not sufficient to show on physical examination, probably should be given some weight as a factor in producing frost-bite.

Previous Occupation—Except so far as it affects nutrition, long periods of unemployment does not make the individual more susceptible, nor does previous indoor occupation.

Pathology—A feeling of cold is a reaction of normal tissues. The sensation of cold is associated with increased circulation, evidenced by a healthy pink color. Numbness is the first symptom on prolonged exposure to cold and indicates that the sensory nerves are affected. All superficial sensation, pin prick, touch, heat and cold are diminished and later absent.

4 Maddock, W. G. and Collier, F. A. Peripheral Vasoconstriction by Tobacco. Demonstrated by Skin Temperature Changes. Proc. Soc. Exper. Biol. & Med. 28: 487-488 (Jan.) 1932.

This anesthesia is the dangerous element in frost-bite, because on continued exposure the damage may increase without any other symptoms, until all the soft tissues and bone have been injured. The distal parts, the terminal phalanges, the ears and the nose tip are the parts first affected. I have never seen a middle phalanx or proximal part affected unless the more distal portions were much more seriously involved.

At the onset of the frost-bite there is a constriction of the blood vessels evidenced by pallor of the skin. In the early stages this disappears quickly if the part is warmed. In the later stages the skin remains white, later it becomes purplish or black and from twenty-four to forty-eight hours later blebs or chilblains form. Whether these pathologic effects are a direct result of the cold or due to vasoconstriction or a trophic nerve disturbance has been long debated. The fact that the most distal parts of the body, where the blood vessels are small, are the ones affected indicates that a change in the arterial supply is the important factor.

The changes in the skin are a useful but not always accurate measure of the damage to the deeper tissues. The motion of the joints may be restricted, but how much of this restriction is due to tendon injury and how much to injury of the joints it is impossible to state.

The bones are involved in severe cases. In the early stages, this condition is evidenced solely in roentgenograms by osteoporosis. Later, necrosis occurs with sinus formation. The discharge is slight, thin and gray. No pieces of bone are discharged and no sequestra are formed. There is no evidence of new bone formation. In late roentgenograms the joint spaces are narrowed or obliterated.

Histologic sections⁵ of fingers of three patients amputated more than four months after the frost-bite showed edema and round cell infiltration of the skin and subcutaneous tissue. The skin was atrophic and ulcers showed no epithelial reparative process. Small pieces of bone tissue looked amorphous, there was no evidence of new bone formation. In places there was granulation tissue or dense connective tissue repair. The new tissues were less vascular than usual. Some of the sections showed blood vessels with organized

thrombi. The interesting finding is the absence of epithelial or bone repair.

The clinical picture and what is known of the pathology point to an ischemia as the basis of the condition. From a therapeutic point of view, this must be considered the important factor. Even if some or all of the damage is due to the direct effect of freezing or to trophic changes, the only hope of restoration is the reestablishment of circulation as quickly as possible. It is axiomatic that whatever the cause of tissue injury, repair depends on early establishment of adequate blood supply.

Treatment—The treatment was that commonly used in frost-bite, namely, ointments for unbroken skin conditions, sterile dressings for blebs or ulcers. If bone

Chart 2—Temperature humidity wind movement and incidence of frost bite.

necrosis developed, the wound was cleansed and surgical dressings, wet or dry, were applied. Treatment was directed mainly to prevent infection and for that reason is important. Other than preventing complicating infections, it has no influence on the end result.

Secondary infections were treated with the usual surgical dressings. If the condition did not heal but bone necrosis continued for from three to five months amputation was used as a last resort. This is sound conservative therapy and until recently was the only method of treatment available.

Whether the treatment was begun early or late apparently did not influence the end result. In a few cases, if treatment had been requested earlier some days of disability might have been avoided by preventing infection of blisters, but none of these avoidable secondary infections developed to any serious condition.

Comment on Treatment It is possible that exposure in colder climates results in a different condition from

⁵ The sections were obtained through the courtesy of Dr. J. M. Hittorff. They were made by Dr. A. M. Sala whose reports were freely used in this summary.

that seen in New York. Mummification or rapid gangrene is not seen, this no doubt requires other treatment. In our climate the custom of rubbing with snow must be condemned.⁶ In the Alps, snow is soft, dry and clean, on city streets it is gritty, moist and dirty. The first treatment should consist of the application of gentle warmth, best obtained by wrapping the whole hand or foot in wool and thus using local body heat.

Considering the pathology of frost-bite, it seems to be a condition that can be favorably influenced by physical therapeutic methods. Good results have been reported by a number of physicians.⁷ The recent reports of the use of apparatus for passive vascular exercise give the greatest promise.⁸ There is nothing to be lost and everything to be gained by skilful and early use of physical therapy. Indiscriminate application and early use of heat lamps or diathermy, however, is to be condemned. This treatment must be administered by one skilled in physical modalities.

If necrosis of the phalanges takes place, surgical intervention is necessary. Nothing can be gained by procrastination. The wound seldom heals and, if it does the skin becomes so adherent to the bone that amputation is necessary. If a partial amputation must be done the character of the stump is more important than the loss of another centimeter in the length of the finger. The surgeon should bear in mind that a completely immobile finger is a more serious handicap to a manual worker than an amputation of that finger. Consideration must be given to the functional end result rather than to the anatomic loss.

Röntgenograms—Roentgenography of the necrosing bone showed a picture different from septic osteomyelitis. Areas of sclerosis are unusual, indicating that new bone does not form readily.

Contracture of muscle tendons, both flexors and extensors, is the most common of permanent defects. In these cases, roentgenograms show a degree of osteoporosis far greater than in similar contractures due to infectious tenosynovitis, indicating that bone is always directly affected by frost-bite when there is tendon involvement.

Prevention—When work can be postponed, due consideration should be given to hazards of temperatures below 8 F or to temperatures between 8 and 14, when there is a very strong wind. Where the work permits, indoor rest periods of a half hour every two hours should be used. A worker who develops numbness and blanching of the extremities should discontinue work for the day. Attention should be given to clothing. It should be well fitting but not excessive. Gloves, socks and shoes are more important than body clothing to men who do hard labor. One good pair of well fitting gloves or preferably mittens will protect the hands better than a tight fitting double pair. Shoes that fit with one pair of socks may be too tight with two pairs. In preventing frost-bite, fit of gloves and foot wear is more important than thickness. Men with cardiovascular disease or diabetes should be excluded from outdoor work at low temperature.

Complications—It is surprising that rhinitis, tonsillitis or pneumonia were not reported as complicating

any of these frost-bites. No cases of aggravation of tuberculosis or other systemic diseases were found.

SUMMARY

Three hundred and eighty-eight cases of frost-bite occurred among employees of the Sanitation Department of the City of New York during the winter of 1933-1934. Analysis of the weather conditions during the days of exposure showed that temperatures below 14 F constitute an industrial hazard to outdoor workers, high winds add to the risk, humidity is not a factor. Older men are not more susceptible except as they have cardiovascular disease or diabetes. General nutrition and clothing are of importance, more important than any other factor is the length of exposure after the first symptoms appear. Improved methods of treatment should be sought especially in the field of physical therapy.

CLINICAL MUTATIONS IN LYMPHOBLASTOMAS

UDO J WILE, M.D.

AND

FRANK STILES JR., M.D.

Professor of Dermatology and Syphilology and Instructor in Dermatology and Syphilology. Respectively University of Michigan Medical School

ANN ARBOR, MICH.

For years a group of diseases, now generally classed as lymphoblastomas, have been studied and interpreted as separate and distinct entities. This group comprises chiefly mycosis fungoides, Hodgkin's disease, lymphatic leukemia, lymphosarcoma and the subvarieties of these. Not only were these conditions considered quite separate one from another but there existed a wide difference of opinion regarding the interpretation of the clinical and pathologic changes in any one particular member of this group. To complicate an already chaotic state of affairs, cases appeared from time to time that possessed features of two or more of these diseases. Adding to this the widely varied and multiform lesions presented by any one condition made the confusion complete.

In recent years a semblance of order has emerged from the chaos with the growth of the view that these conditions are all genetically related neoplasms involving the lymphoid tissues. One of us¹ has repeatedly emphasized this view in various discussions of the lymphoblastomas and has pointed out that one variety may merge into another. There are those (Ewing,² Ormsby³) who believe that more is to be accomplished by separating these diseases into distinct entities. However, it seems that a clearer understanding may be had by recognizing the features that these conditions have in common and their possible relationships.⁴ It is to

add further evidence to the view that the various members of the lymphoblastoma group are but different manifestations of an underlying lymphoblastomatous process that this paper is being presented.

The fact that granulomatous-appearing lesions occur in the skin during the course of these diseases has led to the view that the probable etiologic agent would be found to be infectious (Ormsby,⁵ Macleod,⁶ Ewing²)

Fig 1—Patient when first seen in 1921 with infiltrated nodules and plaques characteristic of the prefungoid stage of mycosis fungoides

Support for this view was found in the fact that the histologic picture seen in the lesions showed a connective tissue proliferation with an accompanying infiltrate of lymphoid cells suggesting chronic infectious granuloma. A great amount of bacteriologic and immunologic investigation has been carried out in attempts to establish or rule out an infectious agent in Hodgkin's disease, leukemia and mycosis fungoides (Zinsser,⁷ Fox,⁸ Fraser⁹). Although Hodgkin's disease and leukemia are believed by some to be associated with tuberculosis, pneumonia and various acute infections (Reed,¹⁰ Longcope¹⁰ Ewing²), no definite etiologic organism has been established.

On the other hand Warthin¹¹ in a study of a vast amount of biopsy and autopsy material concludes that

these diseases are all related neoplasms. They show metastasis and infiltration. They run a similar course with remissions and recurrences. He states further that fever occurs only when there is absorption of necrotic material when there are no cures and no immune reactions and when there is a steady malignant progress to fatal termination.

The same histologic picture that is interpreted by some (Ormsby,⁵ Macleod⁶ and others) as inflammatory—namely connective tissue proliferation and an infiltrate of lymphoid cells—has been considered by an increasing number of observers as a neoplastic process.

Keim¹² writing from this clinic has pointed out that in all members of the group of clinical lymphoblastomas there is an infiltrate of abnormal cells of the lymphocyte series differing in individual cases in the degree of maturity of these cells. The connective tissue proliferation is to be looked on as a stroma reaction to the presence of the tumor cells such as is seen in other types of neoplasms. In the early slow-growing stages the connective tissue response is more marked giving the appearance of inflammatory tissue, while in the later stages when the tumor cells are rapidly proliferating the stroma is seen to be not so well developed.

Fraser¹³ and Keim¹² state that although the early lesions are inflammatory in their appearance, small groups of neoplastic cells may be found after careful search.

The view expressed by Keim from the clinical standpoint is also held by Warthin^{11a} from the pathologic point of view, namely that these diseases are all related and have in common a cell of the lymphocyte series as a type cell. The various types of lymphoblastoma differ

Fig 2—Same patient as in figure 1 twelve years later. The prefungoid lesions had disappeared leaving only scaly and pigmented residua. One eroded nodule is seen on the posterior surface of the right thigh.

¹³ Fraser J F The Interpretation of Mycosis Fungoides as a Variety of Lymphosarcoma Arch Dermat & Syph 11:425 (April) 1925

chiefly in the degree of differentiation shown by these cells. Keim¹² points out that, in his series of cases, the pathologic changes in the various clinical types of lymphoblastoma are interchangeable. Montgomery,¹⁴ in a study of the malignant erythrodermas states that even though the histologic picture in early cases is typical of lymphoblastoma, it is impossible to prognosticate which type will eventually develop.

In a recent paper on mycosis fungoides Ormsby² outlines certain differential points by which the mem-

states that Hodgkin's disease represents a scirrhus form of lymphoblastoma and that leukemia is a lymphosarcoma with tumor cells proliferating in the blood stream.

Recognizing that the various types of lymphoblastoma are but different manifestations of the same malignant process makes possible an understanding of those cases in which features of two or more of the lymphoblastoma group are present, or in which mutations from one type to another occur. Conversely, the presence of two or more of these types in one case, or the presence of mutation from one type to another in one individual adds great emphasis to the view that they are simply different phases of the same process.

Cases that show transitions from one type to another are not rare in the literature. It has been pointed out that the proliferating tumor cells may eventually gain access to the blood stream and thus give an associated picture of lymphatic leukemia. Keim,¹² Symmers,¹⁷ Fraser,¹⁵ Lane,¹⁸ Pardee and Zeit,¹⁹ have recorded such cases. Symmers²⁰ believes that Hodgkin's disease is separate from the other members of the group but many cases of Hodgkin's disease are undistinguishable from mycosis fungoides. Fraser⁸ has reported cases of mycosis fungoides terminating in typical Hodgkin's disease. Cases of lymphatic leukemia and of mycosis fungoides terminating in lymphosarcoma have been recorded (Fraser¹³ Keim¹²).

The following case shows the definite mutation that occurs between types of lymphoblastoma.

Fig. 3—Section of the original lesion under low power showing marked acanthosis and bandlike infiltrate of cells compatible with diagnosis of granuloma fungoides.

bers of this group may be separated. He states that mycosis fungoides involves chiefly the skin with a mixed cell infiltrate, spares the mucous membranes and only later involves the lymph glands, and that lymphosarcoma usually involves the lymph glands and mucous membranes primarily and presents a fairly uniform type of cellular infiltrate. Leukemia appears primarily in the blood stream only later involving other structures and Hodgkin's disease involves chiefly the lymph glands with a mixed type of cells and connective tissue proliferation later involving the skin and other structures.

These differential points while serving to classify clinical types or stages of lymphoblastomatous development actually point to the underlying pathologic unity of these conditions since they all originate in lymphoid or in reticulo-endothelial tissue. Montgomery,¹⁴ Fraser¹⁵ and others consider mycosis fungoides to be a neoplasm originating in the reticulo-endothelium of the skin. Lymphosarcoma presents a more highly differentiated type of cell originating in the lymph nodes. Mallory¹⁶

members of the family, there was no history of cancer, tuberculosis or syphilis in the family.

The patient had been married for one year. His wife was well and had not been pregnant.

The patient had had all the common childhood diseases with good recovery. He had had occasional sore throats but no other illnesses. He stated that he had never had any venereal diseases.

Five years prior to admission a patch the size of a dime (18 mm) appeared on the left flank. This gradually enlarged and spread to involve the entire trunk and extremities down to the elbows and knees. The pruritus had been most marked

in the axilla with the resulting diminution of thickness of the lesions and a decrease in pruritus.

One year later the patient returned with a recent recurrence of the pruritus but otherwise much the same as before.

A year and a half ago (1933), the glands became enlarged particularly in the left axilla. He was examined in a Toledo hospital and was given roentgen therapy.

Biopsy of the skin at this time showed 'lymphoblastoma cutis with no heavier infiltration than in 1921 but with marked atrophy of the skin'.

Biopsy of a lymph node showed advanced Hodgkin's disease of the lymphoblastoma type. Numerous Dorothy Reed cells and many eosinophils.

Re-examination in 1933—The patient, now 37, was well developed and nourished and was not acutely ill. He presented a generalized eruption consisting of scaly papules and plaques that varied in size from pea sized to double palm size. These were slightly elevated and brick red fading off to a brownish color. The eruption was most marked around the flanks, in the groins, popliteal spaces and axillae and on the upper part of the chest, upper part of the back and the face. There were a few lesions in the posterior hair line of the scalp. Other areas of the body were involved but much more sparsely with much normal skin between the lesions. The lesions themselves were a brick red slightly elevated and covered with fine scales. The skin over these lesions was thin and wrinkled. Numerous small pea sized nodules that were slightly more elevated than the remainder of the skin and somewhat infiltrated on palpation occurred in the larger plaques, chiefly on the inner surface of the right thigh and on the medial surfaces of the forearms. These were slightly more erythematous than the surrounding tissue and were rather firm to palpation. One of these lesions on the posterior surface of the left thigh was eroded and covered with a serohemorrhagic crust. The palms and soles

Fig 5—Section of skin nodule under low power. Biopsy taken in 1934 showing loss of rete pegs and dense cellular infiltrate limited to the upper corium.

in the last two years during which time the eruption had become the most generalized. The condition had been treated locally in conjunction with mercury and arsenic by mouth.

Examination—The patient was well developed and nourished. The scalp was clean. The pupils were round and equal. They reacted to light and in accommodation. The extra-ocular movements were normal. The skin of the upper arms, thighs and trunk presented a profuse eruption made up of many types of lesions. There were various sized light brown pigmented macules and flat papules, some of which were scaly and still others deeply infiltrated forming small nodules and larger thick plaques. The color of all these lesions varied from a pale brown to a rather deep brownish purple. There were a number of scratched papules and linear excoriations. The outstanding characteristic was the polymorphous nondescript, markedly pruritic nature of this condition with the tendency to formation of infiltrated nodules and plaques.

The mucous membranes showed no eruption. The lymph glands were palpable as split pea to pea sized nodules but were not enlarged or tender. The long bones were normal. The spleen and liver were not palpable. The heart and lungs were normal. The deep tendon reflexes were present, equal and normal.

The diagnosis was the prefungoid stage of mycosis fungoides. Biopsy of the skin at this time showed well advanced lymphoblastoma cutis.

Course—During the next few weeks the patient received mild irradiation to the entire body and particularly to the thickened

Fig 6—Section of the same nodule under medium high power showing characteristic changes of Hodgkin's disease with numerous eosinophils and the Dorothy Reed type of giant cells.

were not involved and most of the scalp was free. There were no lesions on the mucous membrane.

The lymph glands showed generalized enlargement varying from the size of a pea to that of a hickory nut. The largest glands being found in the left axilla forming a clump of glands approximately half the size of a fist, each gland being somewhat rubbery in consistency but more or less discrete. The glands in the inguinal region were about bean size.

The liver was slightly tender and the edge could be felt about one fingerbreadth below the right costal margin. The edge was soft. The spleen was not felt.

The bones and joints and tendon reflexes were normal. Roentgen studies revealed

1 Abnormal opacity of the second lumbar vertebra. We believe that lymphoblastomatous involvement is the most likely explanation.

2 No demonstrable abnormality in the long bones.

3 Old calcified tuberculous lesions in both apexes and right base—the chest otherwise was normal.

4 A barium sulphate enema revealed a normal colon.

Results of the examination of the blood are given in the accompanying table.

Examination of the Blood

Date	Blood Studies			Differential					
	Red Blood Cells	Hemoglobin, per Cent	White Blood Cells	Polymorphonuclears per Cent	Polymorphonuclear Eosinophils	Polymorphonuclear Basophils	Small Lymphocytes	Large Lymphocytes	Monocytes
11/25/33	4,300,000	79	11,000	79.5	1.0	0.5	12.5	5.0	5.5
12/27/33	4,000,000	77	8,400	70.0	3.5		9.0	12.0	9.5
2/6/34	3,970,000	72	4,000	61.5	6.0		5.5	13.0	13.5
									0.5

Since the last examination the patient has received superficial roentgen irradiation to the skin and high voltage therapy to the entire glandular system with subsequent relief of the pruritus and a diminution of the size of the lymph glands. Within the last few months the patient has returned with several new nodules. Biopsy of one of these revealed a similar picture to that presented by the previous biopsies with the exception that there were numerous eosinophils and giant cells with hyperchromatic nuclei.

COMMENT

This case when first examined in 1921 presented the typical picture of the prefungoid stage of mycosis fungoides. The skin was chiefly involved, the mucous membranes, lymph glands and viscera being spared clinically. The skin presented pruritic, pigmented and dully erythematous plaques and nodules, which showed fine superficial scaling. The microscopic examination of the skin showed a mild acanthosis and parakeratosis in the epidermis. In the corium there was a papillary and subpapillary infiltration of lymphoid cells of a mixed type resting on a connective tissue reticulum. In all respects this case conformed to the picture of early mycosis fungoides.

Recently the lymph glands became enlarged and tender. There also appeared low back pain, which at first was interpreted as lumbosacral strain. Roentgen studies of the lumbar spine showed an increase in density in the second lumbar vertebra suggestive of a metastatic malignant growth. Microscopic examination of the lymph glands at this time revealed a rather marked fibrosis, numerous eosinophils and Dorothy Reed type of giant cells characteristic of Hodgkin's disease. The most recent biopsy of the skin showed numerous eosinophils and giant cells in addition to the mixed cell infiltrate previously described.

The case originally presented the features emphasized by Ormsby in the differentiation of mycosis fungoides from the other lymphoblastomas while at a later date it gave the characteristic changes of Hodgkin's disease. If one is to believe that the two conditions are distinct entities there are but two ways to explain this case: first, that it is a case of mycosis fungoides in a patient who has later developed Hodgkin's disease also; and second, that the disease was originally a case of

Hodgkin's disease which was at first misinterpreted as mycosis fungoides and only later recognized.

The first explanation seems a poor one, since it requires two diagnoses to explain a condition that has been continuous. In the light of the material pointed out in the early part of this paper, it must be observed also that the underlying pathologic processes have retained their essential features throughout, namely, the fibroblastic proliferation and infiltration of lymphoid cells. The microscopic picture in the skin itself did not vary in essential details.

The second explanation also seems inadequate since this case in the early part of its course possesses all the characteristics that identify the premycotic stage of mycosis fungoides as an entity.

A more logical explanation and one that is easier to understand is that this case presents a malignant disease of the lymphoid tissues, first involving the lymphoid structures in the skin and producing the picture that is recognized as mycosis fungoides, and later involving the lymph glands themselves producing the picture that dermatologists have learned to classify as Hodgkin's disease.

As pointed out previously in the slow growing types of lymphoblastoma there are apt to be more fibroblastic proliferations. Fibrosis in the lymph glands in Hodgkin's disease is one of the important diagnostic changes, and this is well marked in this particular case. It is interesting to note that this case has shown unusually slow progress, the known duration extending over a period of eighteen years. It is not improbable that the irradiation received by the patient has been influential in preventing the late picture of mycosis fungoides and may have been influential in the production of fibrosis, which constitutes an important part of the pathologic picture in Hodgkin's disease.

SUMMARY AND CONCLUSIONS

1 A case of unusual duration showed definitely a mutation from clinical mycosis fungoides to Hodgkin's disease.

2 Clinical mutations that occur between the various types of lymphoblastomas constitute strong evidence in favor of the view that lymphoblastomas are genetically related neoplasms involving the lymphoid tissues.

3 It is possible that irradiation may have influenced the course of the disease.

201 South Main Street

APPENDIX—Since the writing of this paper, the patient developed an enormous increase in size of all his superficial lymph glands and died with a typical clinical picture of Hodgkin's disease.

ABSTRACT OF DISCUSSION

DR. HARTHER L. KEIM, Detroit: With the presentation of this case the authors have forged a link in the ever increasing lengthy chain tending to support the interrelationships between these various lymphoblastomas. The clinical evidence here presented with reference to the mutation of a case of granuloma fungoides into Hodgkin's disease seems to me almost incontrovertible. The evaluation and interpretation of the diseases of the hematopoietic system have been one of the major medical problems in recent years. Dermatologists are especially interested in the cutaneous aspects of four of these lymphoblastomas, namely, leukemia, granuloma fungoides, Hodgkin's disease and lymphosarcoma. Ten years ago in presenting a case of leukemia cutis before this section I made reference to the genetic relationships that existed between this group of clinically divergent dermatoses. It was suggested then that much could be gained by a proper classification of this group of widely

divergent clinical manifestations. Five years later, twenty cases of lymphoblastoma with ten autopsy reports were recorded and their interrelations discussed. In this group the striking similarity of the cutaneous microscopic picture was stressed and two consistent features were emphasized, namely the background of the connective tissue stroma varying in density, and the cellular infiltrate first occurring in the so called cutaneous lymph nodes, and later the infiltrate increasing being of the lymphocytic series to produce the characteristic fully developed bandlike infiltration as seen in all these lymphoblastomas in their later stages. Discussion still exists as to the nature of these lymphoblastomas. It has always seemed to me that they are not infectious but rather neoplastic in nature. In support of this hypothesis four facts are of interest. (1) This group of diseases is invariably fatal. (2) they spread by infiltration. (3) they are essentially destructive. (4) they have no protective function. In short, they have the characteristics of neoplastic disease and none of the characteristics of infections. It is simpler and more natural to correlate these diseases than to strain at the impractical and artificial task of attempting to separate them into clinical and anatomic entities.

DR. GEORGE M. MACKEE, New York. The authors have added to existing knowledge a definite instance of mutation in that a case of mycosis fungoides showed Hodgkin's disease of the lymphatic glands. Both the clinical and histologic features of lymphoblastomas are often confusing. Occasionally these features are sufficiently definite for designation of one particular member of the group but not infrequently it is necessary to hedge and make a diagnosis of lymphoblastoma. Occasionally one encounters an eruption that both clinically and histologically is definitely identified as an inflammation—psoriasis, eczema, parapsoriasis and the like. Later it is proved to be mycosis fungoides. In such instances was the case one of psoriasis that changed to mycosis fungoides or was it one of the prefungoid stage of mycosis fungoides indistinguishable from psoriasis? I favor the latter possibility. This delves into the question of the actual identity of dermatologic entities which is none too secure.

DR. MARION B. SULZBERGER, New York. It might be worth while to call attention to a recent article from the Fischer-Wasels school which was mentioned in an editorial in *THE JOURNAL*. The authors found as a by-product of some experiments with indole poisoning in mice that they could create in the mice different types of disease of the lymphatic system. I looked up the original publication. The protocols were not detailed but the essential features seemed to be that a certain large dose of indole led to lymphadenoses and inflammatory changes in the lymphatic system and when the dose was decreased and given more continuously that is, when smaller doses were persisted with these lymphadenoses began to change into conditions that looked like malignancy. Eventually it became possible to produce true lymphosarcomas which metastasized. I believe such observations may be of great importance and that they may bear some relation to the transition between inflammatory and neoplastic changes such as we frequently see in dermatology and as brought out by Dr. Keim and the authors.

DR. WILLIAM H. GUY, Pittsburgh. There is essential agreement that this is a group of malignant diseases that are genetically related and that the point to be raised is whether or not there is actual development of a separate disease ensuing on a primary disease of a different nature or whether it is a mutation from one form of the disease into another, in other words whether or not these diseases are related not only genetically by virtue of their origin in the reticulo-endothelial system or whether they are diseases of that system but of separate and distinct etiology. An alternate explanation that has to be considered in mutation is the possibility as implied in Dr. MacKee's discussion that long continued insult applied to the skin may be the determining factor that develops an entirely different clinical condition.

DR. FRED D. WEIDMAN, Philadelphia. I don't think there can be any question about the clinical mutations that are comprised in the lymphogranulomas—a number of them are valid entities. When one gets into the pathologic realm, the one of tissue

changes however I think that one can better understand the situation if one first thinks of the changes that take place in fibrous tissue which is only another chronic reactive tissue of the body just as reticulo-endothelial tissue is. Think of the different sequences in the forms of fibrous tissue that may be seen in a nonspecific say chronic inflammatory disease. A fresh scar looks different from an old scar. Some scars are pigmented some are not. Some are depressed. Some are soft and pliable. Yet all are comprised by the same kind of tissue. Histologically there will be variations too, fibroblasts of young scars differ considerably but within limits, from old hyaline collagen bundles. Turning next to the reticulo-endothelial system, I believe that there is a similar plasticity in the type of change that may take place. Reticulo-endothelial means two kinds of cells concerned—those of the lymphocyte series and those of the reticular series meaning that the situation is more involved than for fibrous tissue. The changes that take place in hyperplasias of the reticulo-endothelial system have not been worked out fully as have those in the changes that take place in the fibrous tissue. In that light it can be understood how at one stage or another of a certain pathologic condition there would be purely a reticulosis. I am about to report a case of aleukemic reticulosis which Dr. Wayson sent me from Honolulu with massive infiltrations around the face which were at first regarded as leprosy. At necropsy the bone marrow was found severely involved by a pure reticulosis. I have recently studied some cases of Torula infection in which there were Hodgkin's-like changes and Dr. Wile recently reported in New York a similar case. In torulosis and yet other cases like the middle intoxication that Dr. Sulzberger spoke of, there may be a definite etiologic starting point from which to begin in trying to test out whether different gradations in reaction of the reticulo-endothelial reaction may take place. This parallelism with fibrous tissue reactions is something that I think ought to be kept more closely in mind as one studies these lymphogranulomas. I believe that the concept of the lymphogranulomas is well founded as a group, that for the time being it is proper to recognize clinically the differences between granuloma fungoides and Hodgkin's disease. They are convenient designations to employ in medical conversations, but when more is known about the details of the histologic or biologic changes of the reticulo-endothelial apparatus, it will be found that they are not etiologic entities.

DR. FRANK STILES JR., Ann Arbor, Mich. Cases of psoriasis have been reported, cases of parapsoriasis and other relatively benign dermatoses, which have changed into lymphoblastoma. In fact, at the present time one or two cases have been observed in the University Clinic which are just on the fence so to speak they appear to be making this particular transition at this time. As to Dr. Sulzberger's point I have no experience with that particular portion of the question, and so I have nothing to add to his remarks. Dr. Keim covered most of the material which I planned to use in the closing talk and I just want to point out further that these mutations seem to be the important connecting link that ties this group together. They are clinically individual diseases which change from one to another and which have a common denominator in an infiltrate composed of abnormal lymphocytes and when one type is seen going into another it lays great emphasis on the fact that they are probably very closely genetically related.

Activation of Foods by Irradiation—Sunshine, like fish oil, is an old remedy for rickets. Its importance, however, was not fully appreciated until Hulschinsky (1919, 1920) by means of radiographs clearly demonstrated the healing action of sunlight and of the light from the quartz mercury arc. Hess, Pappenheimer and Weinstock (1922) determined that the effective wavelengths of light are the shorter ultraviolet waves of the solar spectrum or the still shorter waves of artificial sources. Goldblatt and Soames (1923) discovered that the livers of irradiated rats when fed to nonirradiated rats, convey some of the virtue of irradiation to the animals which eat them. This, in greatest brevity is the background for the discovery of the activation of foods and sterols by irradiation—Bills, C. E. *Physiology of the Sterols, Including Vitamin D*, *Physiol Rev* 15:1 (Jan) 1935.

SIDEROFIBROSIS OF THE SPLEEN IN
SICKLE CELL ANEMIA

L. W. DIGGS, M.D.

MEMPHIS, TENN.

The pathologic condition of the spleen in sickle cell anemia is characterized by a series of progressive changes from congestive enlargement to fibrotic atrophy. The gross and microscopic appearances of spleens examined at different intervals in this process are varied and apparently dissimilar. The descriptions of the thirty-three spleens available in the literature¹ are mostly in the form of single case reports by different authors and with few exceptions they are brief and lacking in essential details. It is difficult to obtain from these descriptions a clear concept of the sequence of events or a picture of the process as a whole. It is my purpose in this paper to describe the lesions of the spleen in sickle cell anemia, to trace the develop-

Bothe, Waltz, E. C. Smith, Lash, Cooley, Bennett, Mathews and Corrigan for aid in the assembling of sufficient material to make possible the study of a consecutive series. Assistance in the interpretation of the microscopic examinations was given by Dr. R. E. Chung, instructor in pathology, and the photomicrographs were made by Mr. J. G. J. Perkins, Jr., photographer, at the University of Tennessee Pathological Institute.

The earliest demonstrable lesion in the spleen in sickle cell anemia is congestion of the reticular spaces with sickled erythrocytes, and dilatation of the capillaries in the malpighian corpuscles. The spleen representative of this stage is enlarged, dark purple and soft. The surface is smooth, the capsule and trabeculae are thin and inconspicuous, and the splenic corpuscles are indistinct.

On microscopic examination the splenic cords are stuffed with entangled masses of greatly elongated, pointed, curved and bizarre shaped erythrocytes, which render the nuclear structures and reticulum relatively inconspicuous. The sinusoids are for the most part compressed and empty. Brown and black pigment granules, giving a variable reaction for iron, are present in small quantities, free and within the cytoplasm of the pulp phagocytes and the endothelial cells of the sinusoids. The splenic corpuscles are small, their germinal centers absent or atrophic. There is intense congestion of the pulp at the margins of the corpuscles. In some cases, but not in all, the capillaries of the malpighian bodies are dilated, so that they appear as multiple small varices or as one or more great pools of blood lying within or at the edge of the lymphoid aggregates.²

In the areas of intense congestion in the region of the terminal arterioles hemorrhages occur. Sickled erythrocytes are found in the reticular spaces of the splenic corpuscles, around the central arterioles and in the peripheral trabeculae (fig. 1). As the perivascular hemorrhages organize, the vessel walls become greatly thickened and there are pigmentary changes and depositions of mineral salts. The lumens of the vessels become narrowed, owing to intimal hyperplasia and to subintimal hyalinization. In these narrowed terminal vessels in which there is stasis and around which there is an inflammatory reaction, thrombi readily form.

Infarcts are common. They are usually multiple and small, spherical or wedge shaped, dull gray and surrounded by congested pulp. Thrombi in the larger arterial branches are rare but massive infarctions do occur. On organization the areas of infarction are replaced by fibrous tissue, usually without calcification or extensive pigmentary changes.

The picture presented by the spleen during the stage of organization of hemorrhages is complicated, varied and colorful. The lesions do not all progress at the same rate. Congestion, hemorrhages, infarcts and organization may occur simultaneously. The spleen representative of the early stages of fibrosis is still enlarged but becomes progressively smaller. The surface is nodular, owing to depressed scars and elevations of the still congested areas. The organ is firm, and on sectioning the knife meets with resistance. The capsule is irregularly thickened and the trabeculae are prominent. The dark purple characteristic of the highly congested stage is now replaced by a lighter, more slate-

ment of the process and to correlate the changes found with the clinical picture and with similar manifestations in other diseases.

The material on which the work is based consists of an analysis of the literature dealing specifically with the pathology of the spleen in sickle cell anemia and a study of nineteen spleens from patients with active sickle cell anemia. Four of these spleens were removed at autopsy at the Memphis General Hospital. The rest were obtained from other workers who, on request for material from their reported cases, kindly furnished blocks or sections. I am indebted to Drs. Sternberg,

From the Department of Pathology, Pathological Institute, University of Tennessee.

Read before the Section on Pathology and Physiology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

like color with tints of brown and localized areas of gray. Scattered throughout are numerous yellowish brown nodules varying in size from barely visible flecks to masses from 1 to 2 mm in diameter. These nodules are hard, irregular in outline and firmly attached to the surrounding tissues and give the appearance of embedded granules of rust.

Microscopic examination of these yellow-brown nodules reveals localized units of connective tissue con-

and segmented arrangements, appear and mingle with the blue staining fibers or are continuous with them. As the process advances, the connective tissue becomes more dense and there is hyalinization. The erythrocytes disappear. Highly refractile masses of brown pigment with varying tints of yellow and green lie in the tissue spaces. These brown structures are often segmented and resemble bamboo sticks (fig 4). They may appear as irregular crystals or as cylinders having spherical knobs at their tips. They are often infiltrated with iron and calcium salts and consequently present varying combinations of color in the stained sections. Large roundish masses, ranging in color from greenish blue to black having lamellated, fissured or double contoured structures, are conspicuous (fig 4). Foreign body giant cells are numerous and may lie in proximity to or encircle any of these constituents.

The organization of the periarterial hemorrhages in the trabeculae is accompanied by tissue changes similar to those found in the splenic corpuscles, except that the pattern of the iron and calcium incrustations follows that of the elastic fibers of the trabeculae. One sees slightly wavy or straight spindles, parallel to one another and to the longitudinal axes of the blood vessels. These vary in number from a few strands to solid calcified bundles. At the point where the trabeculae join the siderotic nodules, the filaments appear as radiating splinters or surround the vessels in a distorted arrangement (fig 2). In the later stages the calcified structures bulge out into the narrowed lumens of the vessels or may completely block them.

Fig 2—Beginning siderofibrotic nodules in the spleen in sickle cell anemia. Organization of hemorrhage in trabeculae and at sites of splenic corpuscles with pigmentary changes and iron and calcium incrustations. Reduced one fifth from a photomicrograph with a magnification of 40 diameters.

taining conspicuous hematoxylin staining masses and brilliant pigmentary deposits. These colorful units are usually in contact on one side with the trabeculae, with which they are continuous and from which they project out into the congested pulp (fig 2). In the early stages, nodules completely surrounded by pulp are occasionally seen. The shape of the nodules is extremely variable, and the irregular margins are poorly defined and merge in a nebulous manner with the zone of erythrocytes (fig 3).

The sequence of tissue changes taking place in the development of the full blown nodule is as follows. First there is proliferation of fibroblasts in the hemorrhagic area around the central arteriole. Leukocytes wander in and there are large quantities of yellow-brown granules. The pigment granules are phagocytized by the elongated fixed tissue cells and by the large mononuclears. The connective tissue cells and pigment laden phagocytes undergo degenerative changes. Delicate wavy and branching filaments taking a solid or granular hematoxylin stain and having the pattern of reticulum appear in and about the extravasated sickled erythrocytes. These filaments become thicker, often are segmented and in places form tangled masses. They lie as brushlike structures in the organizing hemorrhagic zone or encircle the vessels as a dense network (fig 2). These blue staining structures give the chemical reactions for calcium and iron and will be referred to as calcium and iron incrustations or depositions of mineral salts. Green filaments, likewise with branching

Fig 3—Siderofibrotic nodule. Reduced one fifth from a photomicrograph with a magnification of 450 diameters.

As the organization of the hemorrhages proceeds, at the sites of the malpighian bodies and in the trabeculae there is an increase in the pulp reticulum and a relative decrease in erythrocytes. Ultimately the pulp becomes completely replaced by fibrous tissue, and the pulp, the remains of the splenic corpuscles and the trabeculae become coalesced into a hyalinized connective tissue mass in which the pigment and calcium and iron incrustations are entrapped (fig 5).

The appearance of the spleen in the later stages of the siderotic nodule is that of a small hard, nodular organ of a dull gray. On section one sees wide whitish fibrous tissue strands flecked with yellow and brown. The residual pulp is partitioned off into localized units and varies in color depending on the degree of congestion, fibrosis and pigmentation.

Microscopically the picture is subject to wide variations in different spleens and in different portions of the same spleen. All small firm spleens in sickle cell anemia have in common a great increase in connective tissue, a relative decrease in pulp, an absence of typical splenic corpuscles, depositions of pigment, iron and calcium incrustations, obliterative vascular changes and periarterial fibrosis. The pulp, instead of being a mass of erythrocytes as in the early stages, is now a mass of reticulum between which the packed sickled cells lie in capillary-like spaces. In some spleens the sinusoids are greatly dilated and tortuous and their endothelial cells are hypertrophied. Pigment granules are conspicuous in the organizing lobules and there is phagocytosis of erythrocytes by macrophages. Giant cells and branching filaments are occasionally seen. Eosinophils, plasma cells and infiltrations of lymphocytes are found. The reticulum of the pulp is continuous with that of the trabeculae, and boundaries are indistinct. The whole picture is one of confusion and distortion of the anatomic pattern (fig. 5).

In the last stages the spleen is reduced to a small wrinkled mass often buried in adhesions. The capsule is greatly thickened and hyalinized. There is no pulp, and pigment is inconspicuous. Thick walled calcified blood vessels with narrowed lumens lie in a mass of disarranged degenerated connective tissue (fig. 6).

Fig. 4—Segmented and branching greenish brown structures and lamellated calcified masses in degenerative connective tissue in siderofibrotic nodule. Reduced from a photomicrograph with a magnification of 800 diameters.

There are few nuclei of any kind and little blood. Finally the last recognizable remnants of the spleen disappear and there is nothing left but narrowed splenic vessels terminating in scar tissue.

Many of the tissue changes just described, such as congestion of the pulp, hemorrhages, infarcts, vascular

changes, siderotic nodules, fibrosis and atrophy, occur in other diseases. The peculiar deformity of the erythrocytes is the one feature that is specific for sickle cell anemia in all stages of the process and is not found in other conditions. It is the combination of sickle cells with the other lesions that makes the spleen in sickle cell anemia unique.

Fig. 5—Later siderofibrotic changes in the spleen in sickle cell anemia. Distortion of anatomic pattern, fibrous tissue replacement of the pulp, mineral salt deposits. Reduced from a photomicrograph with a magnification of 40 diameters.

The siderofibrotic lesions in sickle cell anemia are similar to the siderotic nodules or "Gandy-Gamna bodies" described in hemolytic jaundice, splenic anemia, splenomegaly associated with portal stasis and numerous other conditions. Bennett³ and Jaffe and Hill⁴ were the first to note the similarity of the splenic changes found in sickle cell anemia to those observed in other conditions.

One group of investigators has interpreted the branching and segmented filaments and refractile masses in the siderotic nodule as mycelial structures and has presented evidence supporting the concept of fungi as the etiologic agent in the production of the nodule and of certain forms of splenomegaly. The majority of workers discredit the mycotic theory and hold that the siderotic nodule is the result of the organization of hemorrhages in congested spleens and that the structures morphologically resembling fungi are pigment deposits and iron and calcium incrustations in degenerative connective tissue. Kurotchkin¹¹ and Fasiani and Oselladore¹² for a summary of the voluminous and controversial literature dealing with the siderotic nodule, myelotic splenomegaly, splenic mycosis and the like. This series of spleens from sickle cell anemia patients afforded an excellent opportunity to observe the various stages of development of the siderotic nodule from its inception to its disappearance. Many structures were found bearing superficial resemblances to myeloid structures but our observations of the process as a whole lend no support to the myelotic theory and are definitely in agreement with the chemical or mechanical theory.

The size of the spleen decreases as the vascularity of the organ diminishes as the hemorrhages and infarcts become organized and as the residual pulp becomes replaced by fibrous tissue. There is no direct correlation between the size of the spleen and the age of the patient. In general, the largest spleens are found in infancy and in early childhood, and small spleens are the rule in older children and in adults but there are notable exceptions. Large congested spleens and small atrophic spleens have been found in infants and in adults, which indicates that the active disease may occur in varying age periods or that the rate of progression of the lesions is highly variable. The progressive decrease in size from a definitely palpable organ to one not palpable within a few years' time and a decrease in size following an acute febrile attack have been

to be expected cannot be made at the present time but as the evidence now stands, and in spite of enthusiastic early reports, there is no proof that splenectomy causes a sustained improvement in the anemia or alters in any way the clinical course of the disease. Patients with sickle cell anemia are had operative risks. If left alone, they will in effect "splenectomize" themselves without the benefit of surgery.

ABSTRACT OF DISCUSSION

DR. JOHN C. CORRIGAN, Boston. It appears reasonable to conclude that, in sickle cell anemia, fibrosis with atrophy represents the ultimate stage in the changes that occur in the spleen. At the Boston City Hospital, a Negro, aged 23 years who presented all the characteristic features of this disease including the so-called abdominal crises was found at necropsy, to have a spleen that could be identified by tracing the splenic artery. There was a progressive diminution in the size of the artery with thickening of the wall and narrowing of the lumen as it approached the hilus of the spleen. The organ was atrophic in appearance and weighed 0.87 Gm. When the spleen was sectioned many small foci of calcification were encountered. The surface had a small brownish gray appearance, and normal markings were absent. The capsule of the spleen was wrinkled. The parenchyma was composed of many trabeculae crowded together and a small amount of connective tissue. There were scattered areas of calcification in the capsule and trabeculae. The intima of the small arteries was thickened and their lumens were narrowed. No splenic pulp or malpighian corpuscles were present. It is interesting that this patient showed all the clinical manifestations attributed by some observers to splenic infarction. An explanation of the pains occurring in this disease has not yet been found. There is a group in which splenic infarction apparently accounts for the acute abdominal symptoms. The occurrence of abdominal pain in those with splenic atrophy to the degree described by Dr. Diggs and other writers on the subject makes it necessary to search for other explanations. The acute pains in this disease are not limited to the abdomen but may appear in the head, chest or extremities. We have a 27 year old Negro showing abdominal crises, who is also suffering from severe leg pains, followed by numbness and paresthesia in the legs for from three to ten days. This suggests involvement of the spinal cord. As far as I know, no specific changes in the spinal cord have been described. The pains encountered may be part of a thrombotic process of varying locations and degrees.

DR. CHARLES A. DOAN, Columbus, Ohio. I should like to ask Dr. Diggs whether he has observed the precipitation of an acute exacerbation of the anemia in patients with sickle cell disease following a major operation. A young adult female Negro was seen recently in our clinic complaining of typical gallbladder colic and on examination was found to have the characteristic blood changes of sickle cell anemia. An exploratory laparotomy was made by Dr. Curtis. The spleen could not be found at operation, but a gallbladder full of calculi was removed. Within forty-eight hours after the operation the patient developed an acute hemoclastic crisis with marked jaundice and died a few hours later with a high icteric index and a profound anemia. At autopsy a spleen weighing 10 Gm was found enmeshed in fibrous tissue adherent to the diaphragm, and on section the characteristic microscopic changes so thoroughly illustrated by Dr. Diggs were demonstrated. Such a sudden hemolytic exacerbation precipitated by operation, together with certain other features common to sickle cell anemia suggests an analogy to hemolytic jaundice. I am interested to know whether similar observations and similar deductions have been made in the study of the larger material available at Memphis.

DR. L. W. DIGGS, Memphis, Tenn. Knowledge concerning the operative risk of patients with sickle cell anemia is limited. Instances of unexpected deaths during febrile crises and following operative procedures have been observed in this series and are recorded in the literature.

Fig 6.—Section of a 2.4 Gm spleen in sickle cell anemia (Dr. Steinberg's case). Complete replacement of pulp massive fibrosis calcification. Reduced from a photomicrograph with a magnification of 40 diameters.

clinically observed. Complete clinical and autopsy records are not available from which conclusions may be drawn as to the relationship of the splenic lesion to the severity and duration of the anemia.

Splenic infarcts have been found in patients complaining of severe pain in the left upper quadrant.

Splenectomy is advocated by some and used as a means of treatment. Final judgment as to the benefits

ADEQUATE CIRCULATION IN THE EXTREMITIES

ARTERIOGRAPHY AS A TEST FOR DETERMINING ITS
LIMITS PRELIMINARY REPORT BASED
ON THIRTY AMPUTATIONS

J ROSS VEAL, M.D.

WITH THE ASSISTANCE OF

ELIZABETH M McFETRIDGE, M.A.
NEW ORLEANS

In peripheral vascular disease there is, as Mont Reid pointed out in the brilliant address he delivered as the first recipient of the Rudolph Matas Vascular Surgery Award, a vast and as yet almost untouched field of preventive medicine, but that does not alter the fact that prevention is possible only before the catastrophe has happened, never after it has come to pass. In other words, when once gangrene, the terminal phenomenon of vascular disease, is fully established, there can be no talk of prevention and there should, indeed, be little talk of conservatism, for impending gangrene is one thing, but frank gangrene is another and a very different thing. Gangrene will undoubtedly in the future be less and less of a problem among intelligent private patients, among whom, for that matter, it is no very great problem now, but it will undoubtedly always be a serious problem among ignorant and indigent public charges, and a problem, unfortunately which admits of but one solution. Even the most capable of surgeons cannot save a limb that is beyond salvation when it is first seen, and there is no doubt that the surgeon who procrastinates in the presence of frank gangrene however worthy his motives may be, adds to its death rate just as inevitably as does the patient who delays in presenting himself for treatment until his disease is fully established, or who refuses surgery when it is offered to him.

The question, then, in many cases of peripheral vascular disease is not whether to amputate but where to amputate, and that is by no means as simple as it sounds. If amputation is done high, according to the old law of Heidenhain that at a high level the circulation is more likely to be efficient than at a lower level, the percentage of recurrent gangrene is unquestionably less but the mortality is inevitably greater, for in all amputations the mortality is directly proportionate to the nearness of amputation to the trunk. Even if one chooses to ignore the question of future economic usefulness, which is always decreased in high amputations because of the difficulty of fitting a satisfactory artificial limb, one dare not ignore the risk of a heavily increased mortality, and routine high amputation, therefore, is no solution of the problem.

It is quite true that in a large number of cases, perhaps in the majority of cases, the clinical picture is so clear cut that the level of safe amputation is evident and the problem solves itself. But in many cases the clinical evidence is not conclusive or may be grossly inaccurate, and it is this group which has given rise to the various tests which have been devised for determining in frank gangrene the level at which the circulation is adequate and amputation may safely be done. Many of these tests, for one reason or another, are unworthy of practical consideration, but a few, notably

the histamine reaction and the salt solution test, are enthusiastically advocated by some observers, while it is generally agreed that the use of the oscillometer gives a very high percentage of correct results. It is with some hesitancy, therefore, that we describe another test for determining the limits of adequate circulation in a diseased extremity, by direct visualization of the arterial supply, even though attempts along this line have been made for many years and have been unsatisfactory only because no agent was available that was at the same time safe and efficacious.

Some two years ago we began the study of the peripheral circulation in all types of peripheral vascular disease by means of arteriography with a stabilized solution of thorium dioxide, and to date we have used this method in more than 200 cases with increasingly satisfactory results from our own point of view and without immediate or remote harmful effects to the patient.

Our technic, which we have described in detail in previous communications,¹ we need mention only

Fig 1—Diabetic gangrene of toes with obliteration of anterior tibial artery but adequate circulation in upper half of leg. Amputation at site of election with prompt healing.

briefly. The patient lies on the table with the involved limb rotated outward, the leg partially flexed on the thigh, and the knee flat against the x-ray plate. In this position it is possible to visualize on a 14 by 17 film the upper two thirds of the leg and the lower third of the thigh, which is usually all that is necessary. Under local analgesia the femoral artery is punctured in the femoral triangle, and by digital pressure, applied just proximal to the site of puncture, the artery is occluded until the thorium dioxide solution has been introduced, firm pressure being continued until the injection has been completed. At the end of three

From the Departments of Surgery of the Louisiana State University Medical Center and the New Orleans Charity Hospital.

1 Veal, J. R., and McFetridge, Elizabeth M. Surgery of Gangrene of Extremities with a Study of 171 Cases from the Records of the New Orleans Charity Hospital. Surg. Gynec. & Obst. to be published. Technical Considerations in Arteriography of Extremities with Thorotrast. Am. J. Roentgenol. 32: 64-71 (July) 1934. Arteriography in Gangrene of Extremities by Use of Thorium Dioxide (Thorotrast). Study Based on Twenty Seven Cases. Ann. Surg. to be published.

seconds, which allows sufficient time for the solution to be distributed throughout the larger trunks and the smaller branches of the arterial tree, the exposure is made by the technic advised by Dr. Amedee Granger of the Department of Radiology, who has cooperated with us throughout this study. 45 milliamperes, 90 kilovolts, 35 inches, one second. The average dose of thorium dioxide is 20 cc, 15 cc is often sufficient, and we have never found it necessary to use more than 30 cc. Even this maximum quantity, it should be noted, is several

of finer branches visualized is fewer than in the normal state. The lumens are markedly narrowed, and plaques of calcium are often seen in the vessel walls. The existence of a collateral circulation is direct evidence of disease, and its irregularity is characteristic.

From these criteria, which make the distinction between normal and diseased vessels, we have been able to set up other criteria to determine the limits of adequate circulation, which are based on the following considerations:

- 1 The presence of arterial occlusion
- 2 The size of the large arteries above and below the knee
- 3 The number of muscular and skin branches, their size and their distribution
- 4 The efficiency of the collateral circulation

All of these criteria are carefully weighed, both absolutely and in their relation to one another, and the mere existence of arterial occlusion is by no means taken to indicate that the circulation at that level is inadequate; an evaluation of other factors is necessary before the significance of the occlusion can be determined. Thus, to speak specifically, if there is complete occlusion of the tibial artery (figs 1 and 2), but if the arterial tree in the middle or upper third of the leg approaches the normal pattern in the number, size and distribution of the vessels, amputation can safely be done in the upper or even the middle third of the leg. If there is complete obliteration of the popliteal artery (fig 3),

Fig. 2—Arteriosclerotic gangrene of foot with partial obliteration of tibial arteries but adequate collateral circulation. Amputation at site of election with prompt healing.

times less than the dosage established as well within the limits of safety by investigators of unquestioned verity who have used this agent in visualization of the liver and spleen. The injection is painless and nonirritating, and we have never seen the slightest evidence of arteritis or thrombosis, or any other untoward effect.

Our cases are divided into three groups. The first group includes only presumably normal patients and furnishes our standards of comparison. The second group includes patients with arteriosclerotic disease whose circulation is still adequate, and the third group includes patients with frank gangrene. From the study of these groups of cases we have been able to devise certain criteria by which we can distinguish between normal and pathologic vascular states. In normal subjects the most striking characteristic of the injected vessels is the distinct and regular vascular pattern, which fades out gradually as the most delicate terminals are reached, and the orderly arrangement, so to speak, of the arterial supply, which extends to the ends of the toes. All the vessels, furthermore, are visualized, even the fine branches that arise directly from the large trunks. In diseased vessels, on the other hand, the main arterial supply is heavy, uneven, wavy and tortuous. The smaller vessels end abruptly rather than fade out, and the fine branches, which arise directly from the main trunks, are not visualized. The muscular branches are also very irregular, while the number

Fig. 3—Arteriosclerotic disease with obliteration of popliteal artery but adequate collateral circulation.

but if the collateral circulation in the middle and upper thirds of the leg provides an adequate number of skin and muscle branches, amputation can still be safely done below the knee. On the other hand, even though the large trunks should be patent, if the skin and muscle branches are materially diminished in size and number (figs 4 and 5), the circulation is plainly inadequate and amputation must be done above the knee.

In the light of these criteria we have studied thirty consecutive cases of gangrene of the extremities as the

result of peripheral vascular disease, for which thirty-one amputations were done, twenty-three of which, including two on the toes, were below the knee. Four reamputations were required in this group.

CASE 1—A Negro woman, aged 60, had diabetic gangrene involving one third of the foot. Arteriography demonstrated obliteration of the popliteal artery at one point with marked narrowing of the remaining channel as well as of the whole

Fig 4—Arteriosclerotic gangrene of foot with marked sclerosis and narrowing of vessels and diminution in number of muscle and skin branches. Amputation at the lower third of the thigh with healing.

anterior tibial artery. The collateral circulation however was apparently abundant and well distributed, and amputation at the site of election was considered safe. Two days after operation reamputation was done for gas bacillus infection of the stump and the patient did not survive.

CASE 2—A Negro man aged 40 had arteriosclerotic gangrene involving one third of the foot. Arteriography demonstrated the popliteal artery and the large branches to be patent and the lumens to be fairly large while the collateral circulation seemed adequate in both the distribution and the number of the branches. Amputation was done at the site of election and, as in the first case, reamputation was necessary for a gas bacillus infection of the stump. The patient died ten days later, from pneumonia.

CASE 3—A Negro woman aged 60, had diabetic gangrene involving one half of the foot. Arteriography demonstrated the anterior tibial artery to be completely occluded, but the posterior tibial although narrowed, was patent as was the popliteal artery. The collateral circulation appeared to be fairly adequate, and we advised amputation at the site of election, although we believed at the time that our advice was open to question. Events proved the soundness of our doubts, for reamputation was necessary five days after the original operation for recurrent gangrene of the stump. The patient survived.

CASE 4—A Negro woman, aged 63, had arteriosclerotic gangrene involving three toes. Arteriography demonstrated the popliteal and both tibial arteries to be patent, although somewhat narrowed. There was some reduction in the number of skin and muscle branches, and again we consider our advice to amputate at the site of election rather questionable. Five days after the first operation an infection, associated with marked crepitation of the tissues was evident in the stump and reamputation was done on the clinical diagnosis of gas bacillus infection, which was not, however, confirmed by the laboratory. The patient survived.

Undoubtedly all these cases must be charged up against arteriography as a means of determining the limits of adequate circulation, though in the last two we realized, at the time we gave it, that our advice was open to question and the unsuccessful outcome should be attributed rather to our interpretation of the arteriographs than to any defect in the method itself. In the first two cases the gas bacillus infection may have been the result of an external contamination, but since this organism thrives best in poorly vascularized tissues there seems no doubt that we must again assume the responsibility for the mistakes.

Studying the thirty cases from the standpoint of the vascular disease, twenty-one exhibited arteriosclerotic gangrene, eight, in one of which bilateral amputation was necessary, exhibited diabetic gangrene, and one exhibited Buerger's disease. In the last case amputation was necessary at the lower third of the thigh, as it was in seven of the twenty-one cases of arteriosclerotic gangrene. In all the cases of diabetic gangrene, amputation was done at the site of election.

In one case the gangrene was confined to the heel and in nine others to the toes, in only one case in this group was amputation necessary above the knee, and in two cases amputation of a single toe was sufficient. In seven cases a third of the foot was involved, and in two of these amputation was necessary above the knee. In thirteen cases half or more of the foot was involved, and in five cases amputation was necessary above the knee, with three fatalities. In only one of

Fig 5—Arteriosclerotic gangrene of foot with narrowing of popliteal and tibial arteries and rather scanty muscular and skin branches. Amputation at lower third of thigh with prompt healing.

the eight cases, however, in which amputation was done at the site of election, was there a fatal outcome.

The mortality for the whole group of thirty cases is seven, 23.3 per cent, and while the series is too small for fair comparison with the series of 171 cases of gangrene we have recently reported, in which the mortality was 39.1 per cent, or with Chason's series of 175 cases, in which the mortality was 41.8 per cent,

certainly the decrease in the death rate is striking enough to warrant comment. Analyzing the figures more critically, it is noteworthy that the mortality for the eight cases of amputation above the knee is 50 per cent (four cases) as compared with a mortality of only three cases 13 per cent, for the twenty-three amputations done below the knee, even when reamputations are included. Of the wisdom of performing amputation at the lowest possible level there can be no question from the standpoint of mortality. Eliason's mortality of 41.8 per cent is undoubtedly to be at least partially explained by the fact that he does the high amputation in more than three fourths of his cases while in our own series of 171 cases which is large enough to permit of fair comparisons, the mortality for amputation above the knee was 55 per cent, as compared with a mortality of 37 per cent for amputation at the site of election.

As a check on our arteriographs we have used the salt solution test (by the method of McClure and Aldrich) and the histamine reaction test (by the method of Lewis and de Takats) in fourteen cases six of which were cases of frank gangrene that required amputation. In both tests we used eight punctures, running from the middle third of the thigh to just above the ankle. In the histamine reaction test in all cases the first and second punctures indicated

Fig. 6.—Recurrent gangrene of stump. Note narrowing of tibial arteries and diminution in number of muscular and skin branches.

adequate circulation, but in only two cases both without gangrene, did it indicate adequate circulation below the knee. Other observers claim with this test a high percentage of correct diagnoses but in our hands it was clearly open to very serious error. The salt solution test corresponded with our arteriographic studies in 80 per cent of the cases though in one instance it indicated adequate circulation below the knee when both arteriography and dissection after high amputation proved the blood supply to be wholly inadequate. This test, moreover, is valueless when the gangrene is accompanied, as it so frequently is, at least in this hospital by edema and inflammatory reaction. We have no hesitancy in saying therefore, that arteriography is a very much more reliable index of the limits of adequate circulation than is either the histamine reaction or the salt solution test, though we have not had, as yet, an opportunity to check it against oscillometric readings.

On the other hand we make very guarded claims for the worth of arteriography. We by no means claim that the marked reduction in mortality which this group of thirty cases shows, as compared to the mortality

we recently reported in a group of 171 cases of gangrene, 23.3 per cent against 39.1 per cent, is entirely, or even chiefly, due to its use. It is only fair to point out that the majority of these amputations were done in our own service in which it is the policy of the entire staff to surround with every possible protection the patient who has gangrene. We amputate without delay in the presence of frank gangrene, we prepare the patient carefully by the use of fluids by all routes, our postoperative care is equally meticulous, we check the cardiac and renal reserve in all cases, and we handle diabetic gangrene only with the close cooperation of a competent internist. But we do claim that the use of this test, in conjunction with other tests the worth of which has been established, and in conjunction with the proper preoperative and postoperative therapy will furnish one more safeguard for the patient with gangrene of the extremities. Furthermore, since the harmlessness of the stabilized solution of thorium dioxide has been established, and since the injection is only slightly more complicated than the taking of a simple roentgenogram, we can see no objection to the employment of the method at least in those clinics in which radiography of the extremities is part of the routine of the management of peripheral vascular disease.

Clinical Notes, Suggestions and New Instruments

ENTRANCE OF IODIZED OIL INTO THE VENOUS CIRCULATORY SYSTEM DURING UTEROGRAPHY

GEZA WEITZNER, M.D., NEW YORK

Intra-uterine injections of oily opaque substances for diagnostic and therapeutic purposes has become an ordinary everyday procedure in the hands of gynecologists. Very few untoward accidents or sequelae have been reported in the literature to date. The complications most frequently mentioned are peritoneal irritations, localized inflammatory processes, exacerbations of chronic or subacute inflammations in the pelvis and iodism due to the resorption of the customary iodine ingredient of the injected liquid.

The following is a report of an unusual accident occurring during an intra-uterine injection of iodized oil.

M. L., a woman aged 35, a Negress, was admitted to the Sterility Clinic of the Harlem Hospital, March 14, 1932. Her only complaint was her sterile marriage of six years duration. A laparotomy performed seven years before admission, revealed uterine myoma and left salpingitis with adhesions. Appendectomy, myomectomy and left salpingectomy were performed. She had periodic attacks of bronchial asthma. Her husband seemingly was healthy. She had never conceived. Menstruation, which had begun in her sixteenth year, was regular every twenty-eight days, of one or two days duration, scant in amount and not painful.

Gynecologic examination revealed normal external genitalia. The vagina was roomy, the cervix central and conical and the external os was pointed. The uterus was in anteversion-position, was freely movable, was rather small, was of normal consistency and was ovoid. The surface was even. The adnexa were normal. The vaginal secretion was normal. A cervical smear was negative for gonococci. The Wassermann reaction was negative. A condom specimen of the husband's semen examined four hours after coitus showed many motile spermatozoa.

The insufflation test performed March 14, revealed patency at 60 mm. pressure.

From the Gynecological Division of the Surgical Service of Harlem Hospital.

In order to see graphically the effects of the previous operation on the uterus, a roentgenogram was taken, May 1, following the injection of 8 cc of iodized poppy-seed oil. The last menstruation occurred April 27-28. Subsequently the patient reported that instead of the customary staining for a day or so she bled for four days but had no other ill effects.

The immediate picture (fig 1) showed the cavity of the anteverted uterus well filled, the right tube patent, the left tube missing. Free oil was in the abdominal cavity. Besides these normal observations the whole venous system of the uterus was filled with oil, a large quantity being found in the right vena ovarica. The twenty-four hour picture showed some remnants of iodized oil in the free abdominal cavity, the cavity of the uterus and the venous system not visualized (fig 2).

COMMENT

A similar case was reported in the literature recently by Kilroe and Hellman¹. In their case a nullipara was injected with iodized poppy-seed oil. An anteverted uterus was visualized with both tubes patent. The venous system of the uterus was filled with oil and both venae ovaricae were visible. Exactly the same picture was obtained after a repeated oil injection ten days later. The venous system was filled with oil and the tubes were patent. No ill effects were reported after these injections.

Analyzing these almost identical reports one must emphasize that the iodized oil which escaped into the circulatory system was not injurious and did not cause any noticeable symptoms.

To determine the etiology of these accidents, the following possibilities should be considered:

- 1 Excessive pressure during the injection.
- 2 Pathologic permeability of the uterine vessels.
- 3 Injury to the uterine wall.

1 Excessive pressure. This possibility might be excluded on the ground that in both cases the tubes were found patent. Furthermore if excessive pressure alone should be sufficient to produce this occurrence it would be observed much more frequently particularly in cases in which there are closed tubes.

2 Pathologic permeability of the uterine vessels. Kilroe and Hellman are inclined to believe that in their case a pathologic permeability of the uterine vessels was present. They arrived at this conclusion because they obtained identical pictures following the second injection. In their case this explanation is very

suggestive owing to the fact that the uterine circulatory system was entered on two successive occasions. In an attempt to prove this explanation in the present case iodized oil was injected on four subsequent occasions after monthly intervals. On none of these occasions did the oil escape into the circulatory system. Kilroe and Hellman proceeded with their second injection after a ten days interval. In the present case the interval was of one month's duration. Ample time was allowed for the repair of any injured uterine mucosa.

3 Injury to the uterine wall. This seems to be the cause in the present case. It is substantiated by the report of the patient that she had a vaginal bleeding of four days duration after the injection. It would seem that a simple injury produced by the injecting cannula to a normal uterine mucosa

would not be sufficient to facilitate such an occurrence. It probably would require the injury of a venous sinus. In the present case the previously performed myomectomy might have facilitated the injury of such a vessel. In the recent literature over twenty-five lethal cases have been reported following the injection of an oil into the uterine cavity to produce an abortion. Autopsy showed these deaths to be due to an oil embolus.

(Nieslony,² Brack,³ Haselhorst⁴). It must be emphasized again that the iodized oil was not injurious to the patients, whereas the abortion producing oils with their toxic ingredients caused death (Franken⁵).

SUMMARY

1 In a case in which iodized oil was injected into the uterus, the opaque substance filled the entire uterine venous system.

2 Injury to a pre-existing large sinus was the probable explanation for this rare occurrence.

3 The injected iodized oil is apparently not injurious, whereas medicated abortion producing oils have produced death following the same accident.

COSTOVERTEBRAL DISLOCATION OF THE FIRST AND SECOND RIBS

FREDERICK CHRISTOPHER, M.D.

Associate Professor of Surgery Northwestern University Medical School
Chief Surgeon Evanston Hospital

AND

H. R. REICHMAN, M.D. EVANSTON, ILL.

Dislocation of the ribs at the costovertebral articulation is so extremely rare that the present case seems to merit reporting.

Stewart and Warren¹ in 1929 described a case of dislocation of the first rib. They made an exhaustive study of the literature and found only thirteen cases, including their own in nearly two hundred years. These authors presented a brief summary of the reported cases. Since that time Brooksher² has reported another case a dislocation of the twelfth rib. He also refers to Schertlein³ who reported an isolated case of costovertebral dislocation of the first rib. Schertlein states that there is but one recorded case in the German literature from 1909 to 1929 and cites Riedinger who in 1888 compiled nine cases from the literature of which only one case could be regarded as true luxation. Bohle⁴ has since reported two cases making in all a total of nineteen reported cases. Of these the luxations were three cases each of the first rib, twelfth rib and eleventh and twelfth ribs in combination, one case each of the sixth and seventh, eighth and ninth and tenth and eleventh ribs in combination, one case of the sixth, eleventh, fourth and seventh ribs one case in which two of the sixth, seventh or eighth ribs were dislocated⁵ and two cases in which the dislocated rib was not specified.³

Fig. 1—Appearance immediately after injection of iodized oil. anteverted uterus, right tube patent, left tube missing, free oil in the abdominal cavity, the whole venous system of the uterus filled with oil, large quantity in the right vena ovarica.

The case here presented is particularly interesting, as both the first and second ribs were dislocated at their costovertebral articulations, a condition not previously reported

REPORT OF CASE

R L, a white man, aged about 30 was admitted in an unconscious condition to the outpatient department of the Evanston Hospital Aug 10 1934 following an accident in which he and eight others were injured, when a truck which he was driving was struck by a train. Regaining consciousness soon after reaching the hospital, he complained of severe pain in the neck and abdomen. He was very nauseated and vomited several times. There was a laceration about 4 cm in length over the right frontoparietal region bleeding profusely, and marked swelling and ecchymosis around the eyes particularly the right. There was no bleeding or fluid discharge from the ears nose or throat. The neck was held rigid and there was a point of maximum tenderness at the left posterior aspect of the base of the neck near the point of articulation of the first rib with the vertebra. The examination of the thorax was negative. The abdomen was rigid particularly in the epigastrium. The extremities were negative except for several minor abrasions. The deep and superficial reflexes were present and no abnormal reflexes could be elicited.

A leukocyte count taken on admission was 21,000. The leukocyte count diminished until twelve hours later, when it was

Upper dislocation of the first and second ribs on the left side

11,950. The erythrocyte count at that time was 3,800,000 hemoglobin 71 per cent. At no time was the urine examination abnormal.

Because of the serious condition of the patient, no roentgenograms were taken on the night of admission. The indications for laparotomy for a ruptured internal viscus became less each hour. Owing to the patient's persistent complaint of pain in the neck and the possibility of a cervical dislocation or fracture, the head was placed in a halter and three pounds of traction applied to the neck.

A roentgen study of the neck was made on September 13. The roentgenologist Dr E R Crowder, made the following report: "After rather careful consideration I am quite inclined to believe that we are dealing with an upward dislocation of the head of the first and second ribs on the left side. This I realize is a very unusual type of injury and certainly not a very probable injury but I am not able to explain the asymmetry of these ribs in any other way. There is no x-ray evidence of injury to the bodies of any of the cervical vertebrae nor to the spinous processes." Subsequent roentgen examination revealed a fracture of the right frontal bone. With these observations the traction was removed and all active treatment to the neck discontinued.

The patient was treated conservatively for skull fracture with rest in bed and 50 per cent dextrose intravenously as indicated by his symptoms. Open reduction of the dislocated ribs was considered. Because of the head injury, however, any operative treatment that was not imperative was deemed inadvisable.

The patient was closely watched for any impairment of nerve or circulatory function of the upper extremity, but none was observed. The pain and stiffness of the neck gradually disappeared. The patient was discharged on the thirty-fifth day with no complaints. At this time he had full painless motion of the neck and there was no disturbance in function, nor any abnormalities in the left arm.

POTT'S ABSCESS OF THE SPINE OPENING INTO THE BRONCHI

J M FRAWLEY M D AND JEROME W BODLANDER M D
FRESNO CALIF

Cases of Pott's disease of the spine with abscess opening into the bronchi are rare. The history of such a case is therefore reported.

REPORT OF CASE

A Mexican boy, aged 8 years, admitted to the General Hospital of Fresno County June 5, 1933, had had fever and cough for a period of three months. During the last two months the cough had become productive of blood and pus. Three days before admission a high fever had developed. The boy complained of pain in the chest and coughed up some blood. When admitted he was emaciated and appeared ill. The temperature was 103.4 F, the pulse rate 124 and the respiration 26 per minute. There was dullness in the right upper part of the chest and rales were present throughout the entire right lung. The heart was not enlarged and there were no murmurs or thrills. Nothing further was found on examination. The child's father had died of pulmonary tuberculosis.

The laboratory report showed the blood to contain 3,300,000 erythrocytes per cubic millimeter. The hemoglobin was 44 per cent. The white cells were 12,700 of which the polymorphonuclear leukocytes were 75 per cent, large lymphocytes 4 per cent and small lymphocytes 21 per cent. The bleeding time and the coagulation time were three minutes. The specific gravity of the urine was 1.104. It was alkaline and negative for sugar and albumin. Microscopically there were a few leukocytes. The sputum was negative for acid fast bacilli. Roentgenologic examination of the chest showed extensive infiltration in the right upper lobe. Through the entire length of the mediastinum there was a dense fusiform shadow which on fluoroscopy was seen to be posterior. A diagnosis of tuberculosis was made with mediastinitis to be considered. A Mantoux test with 1 mg of old tuberculin gave a 3 plus reaction in forty-eight hours.

The child was isolated and all the therapeutic measures for tuberculosis were instituted. Because of the sitting posture discussion arose as to the presence of spinal caries, and another roentgenologic examination was made. There was considerable rarefaction of the mid-dorsal vertebrae and of the intervertebral space between the eighth and ninth dorsal vertebrae. There was also an infiltration in the adjacent mediastinum. An additional diagnosis of tuberculosis of the dorsal spine was therefore made. After consultation with the surgical staff, it was decided to tap the mediastinum. This was done August 1, and 40 cc. of yellow pus was drawn off. Two days later 65 cc of pus was removed. Smears showed pus and many bacteria, no acid fast organisms were seen. Cultures grew as short chain streptococci and gram-positive bacilli. Guinea-pig inoculations were negative.

In view of the laboratory examination the diagnosis of tuberculous abscess was doubted and the patient was transferred to the surgical section. August 10 in an attempt to drain the abscess an incision was made in line with the ribs in the eighth intervertebral space just to the right of the spinal column. Muscles and fascial planes were separated and forceps inserted into the posterior mediastinum. No pus was obtained. Repeated probing of the posterior mediastinum showed no pus.

The patient continued to have a septic temperature ranging from 97 F in the morning to 104.8 in the evening. His appetite was good however and his cheerfulness was remarkable. August 18 it was noticed that he was developing a dorsal kyphosis and was placed on a Bradford frame. He continued to rest comfortably and had no symptoms excepting cough and fever. September 29 a trocar was introduced into the posterior mediastinum and pus was again obtained. Through the trocar blowing sounds which synchronized with inspiration and expiration, could be heard, indicating that there was a bronchial fistula. No drainage was obtained by means of a rubber tube which was left in place. Postural drainage seemed to help more and was carried out several times daily. The drainage tube was consequently removed.

October 21 35 cc of pus was drawn from the mediastinal abscess and 15 cc of gentian violet injected into the abscess cavity. Almost immediately the patient had a violent fit of coughing and expectorated much of the dye and a quantity of pus.

November 2 he complained of severe pain around the heart. There was marked pulsation over the entire precordial area. The breath sounds were roughened throughout with coarse rales especially over the right lung. The abdomen contained

Appearance of chest showing dense fusiform shadow due to Pott's abscess of the posterior mediastinum communicating with the bronchus.

free fluid and there was tenderness over a palpable liver. The spleen was not palpable. November 4, pus was again obtained by aspiration and a catheter was left in the abscess cavity. About one week later the child coughed up a considerable quantity of pus. His pulse rate went to 144 per minute but was regular and fairly strong. December 9 a longer drain was inserted and irrigations with metaphen 1:4000 were begun three times daily. Two days later the child pulled the drain out. However, the opening was adequate and drainage moderate. He continued to cough and expectorate pus, he was dyspneic and cyanotic and his abdomen was greatly distended until he died, December 14, six months after admission.

At autopsy by Dr. C. A. Nixon both pleural cavities were seen to have extensive fibrotic adhesions. Both lungs showed disseminated tuberculosis throughout with a cavitation about 8 cm in diameter in the right apex and a fairly large area of caseous pneumonia in the left upper lobe. The mediastinum contained very little free pus but did show granulation of the tissues. There was erosion of the vertebral bodies which was so marked that they could be crumpled away with the finger.

COMMENT

Cases of Pott's abscess opening into the bronchial system are reported chiefly in the French literature. In 1928 a case was presented before the Societe de pediatrie de Paris by Mayet

and Genevrier.¹ Their report concerned a boy aged 16 years, who had had Pott's disease of the dorsolumbar spine for six years. After injection of a fistula with iodized oil the boy was seized with violent coughing. The iodized oil was seen on roentgenologic examination to have entered the right bronchus. Apparently some improvement followed this procedure.

Mayet and Genevrier referred to this condition as being extremely rare usually occurring as an accident preceding death. They cited fifteen cases, which were reviewed in the Cremieux thesis (Theses de Paris 1875) but stated that since then very little reference had been made in the literature to such a finding. In the discussion following the presentation of their case a similar incident was reported by Solon Veras who had seen a patient become suffocated and cough up fluid following an injection into a fistulous opening in a Pott's abscess. Lance in the same discussion, voiced the opinion that these cases were not so rare as appeared but were not recognized and might exist in a latent condition. He had once injected hydrogen dioxide into a small dorsal fistulous opening which had persisted for several years following dorsal Pott's disease. The patient had a violent fit of coughing with the expectoration of hydrogen dioxide foam. Lance believes that unless the abscess opens also into the pleural cavities the opening into the bronchus is not a serious menace to long life.

In the case here recorded the diagnosis of abscess opening into the bronchus was not established until the injection of the gentian violet which was followed by an attack of coughing and the appearance of the dye in the mouth.

GLANDULAR PHYSIOLOGY AND THERAPY

GENERAL PHYSIOLOGY OF THE ANTERIOR HYPOPHYSIS

PHILIP E. SMITH, PH.D.

NEW YORK

NOTE.—These articles and those in THE JOURNAL last week are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues of THE JOURNAL.—Ed

Although the general physiology of the anterior hypophysis is inseparable from its special physiology, a general discussion of the recent developments of our knowledge of pituitary physiology may be of value. Experimental and other work is increasingly showing the important position which this organ occupies among the endocrine glands. There appear to be but few body functions that it does not influence either directly or indirectly. Barger has spoken of it as "general headquarters" of the endocrine system, a characterization that aptly expresses its dominant position in this system.

Undoubtedly the large number of contributions that have been published on the anterior hypophysis within the last decade have not simplified but rather have made more complex our knowledge of its physiology. Thus in 1927 two hormones, a growth and a gonadotropic hormone had been demonstrated. The stimulating effects on the growth of normal rats, first shown by Evans and his collaborators,¹ and the pronounced restorative effects of anterior pituitary gland adminis-

tration on growth in rats dwarfed by hypophysectomy,² promised much for the clinical treatment of pituitary dwarfism. The outspoken stimulation of the gonads of miniature normal rodents reported from this country and from Germany (Smith and Engle,³ Zondek⁴) and the reparative effects on the atrophied reproductive organs of hypophysectomized rats⁵ suggested the immensity of a successful clinical treatment of underfunction of the gonads. Indeed, the supra-ovulation obtained at that time³ indicated that such therapy might be too successful and might lead to the liberation of an undesired number of ova. Although the evidence at that time thus indicated that the anterior lobe elaborated two hormones, a growth and a gonadotropic hormone, other observations suggested that the problem might become more complex. Hypophysectomy was found to cause not only an arrest in growth and atrophy of the gonads but also involution of the thyroids and the adrenals in mammals.² It was not known at that time whether the stimulation of the thyroid and the adrenal was effected by the growth or by the gonadotropic hormone or by another pituitary hormone or hormones.

Although it was not demonstrated until this time that ablation of the anterior pituitary caused an involution of the adrenals and thyroids, it should not be overlooked that earlier work (Allen,⁶ Smith⁷) had revealed these responses in amphibia more than ten years previously, and although hyperplasia of the thyroid in birds⁸ and in mammals (Loeb,⁹ Aron,¹⁰ Watrin¹¹) was not described until 1929-1930, hyperplasia of the thyroid from pituitary administration had been secured in 1922,¹² which has not been exceeded in subsequent mammalian experiments. Attention might also be called to the fact that a chromatophore stimulant from the pituitary reported by Zondek¹³ in 1932 and named by him "intermedin" had been demonstrated in 1916 by both B. Allen and P. E. Smith and was subsequently extensively studied by them and other investigators. Indeed a monograph of this subject appeared in 1924.¹⁴ Thus the assumption that, because he applied a new name and emphasized the specific pigmentary reactions of a species of minnow, Zondek uncovered a new hormone is quite erroneous.

THE PITUITARY HORMONES

The growth hormone has continued to be intensively studied since its discovery in 1922 by Evans and Long.¹⁵ It has maintained its position as a separate principle, although preparations of it are usually not pure, physiologically. Consistent results have been reported on its injection into normal rats that had passed the period of maximum rate of growth. The female shows a better response than the male. Marked restorative effects in rats dwarfed by hypophysectomy have been reported from a number of laboratories. Some striking effects in normal dogs have been reported,¹⁶ whereas in other cases no effect was secured even with very prolonged treatment.¹ These different results appear to be due to a difference in the responsive capacity of the end organ (receptor tissues), a phase of hormone studies which is of great importance.

Treatment of a sufficient number of clinical cases has now been reported in which a growth stimulation has been secured to make it seem certain that injections of the growth hormone will be effective, in some cases at least.¹⁷ In these cases treatment was instituted much before the time at which the puberal growth spurt would normally appear, so that a lack of due regard for this factor does not invalidate the results. Unfortunately, this cannot be said of the reports, which still frequently appear, on the stimulation of growth from the feeding of pituitary tablets. The relationship of the pituitary growth hormone to other endocrine glands, especially the thyroid, needs further investigation. It has been reported that the concurrent administration of growth hormone and thyroid gives greater skeletal growth in rats in which both the hypophysis and the thyroids have been ablated than does the administration of the same doses of the growth hormone alone.¹⁸

Although, as already mentioned, it was shown nearly two decades ago in amphibia that pituitary ablation resulted in an atrophic condition of the thyroids and the adrenal cortex and that anterior pituitary replacement therapy would restore these glands to a normal condition, these observations were not confirmed in mammals until 1927.⁵ It has since been shown that administration of anterior lobe causes an enlargement of the thyroid in normal doves and pigeons¹⁹ and a marked enlargement and hyperplasia of this gland together with exophthalmos in normal ducks²⁰ and normal mammals (Loeb and Bassett,⁹ Aron¹⁰ and others). Although the stimulation of the thyroid has not been maintained in chronic treatments, nevertheless these observations are proving of great value, not only in determining whether or not the thyrotropic principle is a separate hormone but also in studying the secretory process of the thyroid gland.

itself. Experimental work indicates that the thyrotropic principle is distinct from other pituitary principles. Among the methods of preparation of this principle, those of Janssen and Loeser²¹ and of Collip²² deserve special mention. The injection of certain pituitary extracts will also prevent atrophy of the adrenal glands after hypophysectomy in rats and will cause their enlargement in normal animals (guinea-pigs). The action of these extracts has been shown to be a direct one, it does not occur through the intermediation of the thyroid, since these preparations do not raise the basal metabolism or prevent thyroid atrophy in hypophysectomized rats.²³ Adrenal enlargement may also be induced indirectly through the stimulation of the thyroids, as shown by Loeser.²⁴ The adrenotropic hormone is ultrafiltrable.²⁵

In 1928 and later, Stricker and Grueter,²⁶ and in 1930 Corner,²⁷ reported that lactation was induced by the administration of an anterior pituitary extract. This was not due to a contraction of smooth muscle of the gland, such as had been reported earlier from posterior lobe extracts. Following this basic discovery of Stricker and Grueter and of Corner, others have studied the reaction more in detail (Asdell,²⁸ Gardner and Turner,²⁹ Nelson and Pfiffner,³⁰ Riddle and his associates³¹ and others). Both Turner and Riddle have worked intensively on this principle, which they respectively have designated as galactin and prolactin. Prolactin or galactin does not cause the development of the mammary gland, this being induced by secretions of the ovary, but it does cause the onset and continuation of the secretory phase. That this is the pituitary galactogogue principle solely responsible for the initiation of lactation is made doubtful by the finding of Selye and his associates³² that lactation, though brief in duration, will take place at parturition in rats that have been hypophysectomized for some days. That the pituitary secretes a hormone either directly or indirectly essential for the continuance of lactation seems established.

One of the questions concerning pituitary physiology which appears to be nearing solution is that in regard to the number of gonad-stimulating hormones. The Wisconsin group (Hisaw and Fevold and their collaborators³³) in a long continued series of investigations

has presented increasingly convincing evidence that the anterior hypophysis secretes two gonadotropic hormones. Supporting evidence has recently also been published from other laboratories. In this work the female has been used largely and this has led to the designation of the two hormones as follicle-stimulating and luteinizing, respectively. These designations, although justifiable at the present state of knowledge, will undoubtedly prove unsatisfactory later, for it is highly probable that if the pituitary secretes two gonad stimulating fractions in the female, it does so also in the male. As in the female, there are in the male two types of gonad tissue. In the male, both these types atrophy after hypophysectomy. Evidence will be presented in a later section which shows that the two types of testicular tissue are stimulated by separate hormones. Although investigators have been slow, largely because of the absence of conclusive evidence in its support, to accept the hypothesis of two pituitary gonadotropic principles, the present evidence indicates that there are two such hormones.

The problem of the unity or duality of the pituitary gonad-stimulating hormones not only is of importance in studies on the physiology of the pituitary but its solution may also give information that will assist in solving the problem of the origin of the gonadotropic principles found in the blood and urine. It is now known that the gonadotropic principle present in the urine (or blood) during pregnancy is different from that present after ovariectomy (or the menopause). They elicit very different reactions when injected into normal rodents,³⁴ hypophysectomized female rats³⁵ or hypophysectomized male rats.³⁶ Pregnancy urine extracts do not cause follicular growth in normal monkeys³⁷ or hypophysectomized rats (Leonard and Smith,³⁸ Collip and his associates³⁹), whereas extracts of urine of women after ovariectomy or the menopause cause marked follicular growth in both these forms. The latter substance appears to give an almost pure gametokinetic action (follicular granulosa and seminiferous epithelium stimulation), whereas extracts of human pregnancy urine stimulate largely the connective tissue derivatives (theca and interstitial cells of the ovary and the interstitial cells of the testes). That pregnancy urine extracts also induce luteinization of the granulosa of the follicle and stimulate the seminiferous epithelium seems established from the work of Smith and Leonard,⁴⁰ although evidence on this point is not harmonious (Collip³⁹). Since extracts of urine of castrates give reactions which are nearly identical with

the purest follicle-stimulating pituitary extracts so far prepared, it seems justifiable to assume that this principle is of pituitary origin. Solution of the problem of whether or not pregnancy urine also contains a gonadotropic principle which is secreted by the anterior pituitary must await fractionation of this principle and comparison of the action of the fractions with physiologically pure gonadotropic extracts made from the pituitary. The problem of the origin of the urinary gonadotropic principles is thus closely related to the problem of the unity or duality of the pituitary gonad-stimulating hormones. This same dependence may be found in studies on the gonad-stimulating principle found in the urine of women (and probably of men also) during the sexually active period of life.

Mention should be made of three other responses that are elicited by injections of anterior pituitary extracts. One of these is the effect on the parathyroid. Little work has as yet been done on the parathyrotropic principle obtained from the pituitary. A pronounced hypertrophy has been reported from its injection.⁴¹ As in the case of the response of the thyroid to injections of the thyrotropic hormone, long continued injections do not maintain the hypertrophy of the parathyroids.

Another action of the pituitary is that on carbohydrate metabolism. In 1930 Houssay and Biasotti⁴² reported that symptoms of diabetes in dogs after pancreatectomy were either cured or alleviated by subsequent hypophysectomy, a finding also reported by Barnes and Regan.⁴³ These results thus extend the observation of Cushing and his associates⁴⁴ that hypophysectomy increased the sugar tolerance. The results are harmonious with and explainable by the discovery that hypophysectomy lowers the blood sugar (D'Amour and Keller,⁴⁵ White⁴⁶), an effect that has been designated as "hypoglycemia hypophysiopriva."⁴⁷ Hypophysectomy is known to increase insulin sensitivity. The further finding that prolonged injections of anterior pituitary extracts (growth hormone, Evans) produce glycosuria in normal dogs, a finding which was reported by Borchardt in 1908 in rabbits, is in agreement with these observations and with the frequent occurrence of glycosuria in acromegaly. Anselmino and Hoffmann⁴⁸ have described a pancreatropic hormone from the anterior pituitary which induces hypertrophy of the pancreatic islands and hypoglycemia.

A more obscure pituitary effect is that on fat metabolism, for which a separate hormone has also been postulated by Anselmino and Hoffmann.

From this brief summary it is evident that no less than six and possibly eight hormones have been extracted from the anterior pituitary. That this small gland which in man averages less than 0.5 Gm in weight, secretes this number of hormones as separate

entities throughout the entire secretory process taxes the imagination. Numerous contributions to the cytology of the normal gland and of cases of tumor formation show that there are but two secretory types of cells—the basophils and the acidophils. The third type, chromophobes, appears to be not an active secretory cell but a reserve type. This differentiation of two highly specialized secretory types of cells in the pituitary suggests perhaps the formation of a corresponding number of basic secretory products, which may be altered to give these specific responses. The chemical interrelationship of pituitary hormones holds an interest equal to that of their physiologic interrelationships.

The present anterior pituitary products are almost without exception extremely crude from a chemical point of view and usually are impure, physiologically. There will be no certainty until physiologically pure extracts are secured as to how much these impurities may modify the responses. The present purified products (for example, purified growth hormone) are purified only in contrast to the earlier souplike preparations. An instructive example of how impure products may lead to erroneous conclusions is afforded by physiologic work on pregnancy urine extracts. In nearly all earlier work with this material, injurious effects on the tubules of the testes were reported. The more concentrated and purified products now available, however, show that even with high dosages there is no injury but probably a stimulating effect on the tubules. To what extent further purification and fractionation of the material will further modify the reactions cannot now be predicted. The realization that conclusive determination of the responses elicited by the various hormones must await the securing of uncontaminated principles does not mean, however, that present studies with cruder products are valueless or should be discontinued. Such studies are essential to progress in purification, for in no other way can the chemist know whether his more or less mutilating procedures are destroying or modifying activity.

ANTIHORMONES

The failure of animals to continue to respond when chronic treatments with certain of the pituitary extracts are given has led to the formulation of a theory that antihormones are formed (Collip²²). A number of investigators have reported that thyroid stimulation is not maintained with continued administration of the thyrotropic hormone (Siebert and Smith,⁴⁹ Friedgood,⁵⁰ Collip²²). A maximum response varying from the fourth to the twelfth or fourteenth day is followed by a depression that may carry the basal metabolism below the normal level, a terminal effect clearly shown by Lee, Teel and Gagnon⁵¹ several years ago. As stated earlier in this paper, the parathyroid hypertrophy from administration of the parathyrotropic hormone also does not persist with continued treatment. There is also a regression in the response of the gonads to pregnancy urine extracts. Collip²² has presented growth curves of hypophysectomized rats showing an abrupt cessation in growth and a subsequent loss in weight after about thirty days with continued treatment with his preparation of the growth hormone. This

cessation of response with continued injections of these extracts he attributes to the formation of antihormones. In support of his hypothesis he presents evidence showing the production of an antithyrotropic substance in the blood of the rabbit, goat and horse. He advances the interesting hypothesis that the production of antihormones may be responsible in certain cases for hypoglandular states. The hypothesis is attractive and has aroused considerable interest.

The evidence on the production of antihormones is not entirely harmonious in regard to the effects of prolonged treatments, especially with growth-stimulating pituitary extracts. In chronic treatments of hypophysectomized rats with growth hormone, prepared from pituitaries of the ox, Evans and his associates¹ report a continued gain in weight for the 120 days of treatment, although there was a slowing down in growth late in the experiment. They do not report, as do the Toronto investigators, a regression following the first month of treatment. I² showed that daily implants of rat pituitaries for seventy days in a young male hypophysectomized rat gave skeletal growth and an increase in weight throughout this period. The results both of Evans and his associates with growth hormone injections and of Smith with implants thus differ from those of Collip as regards the continuance of growth with prolonged treatment. The blood of diabetic patients even though they display some insulin resistance has no greater power to destroy insulin than has blood from normal individuals,⁵² so there is not an antihormone formed in these treatments. It is well known that thyroid administration is effective even when continued for many years.

Loeb⁵³ has reported that the increased mitosis and the hypertrophy which he found in the thyroid on administration of potassium iodide cease after a time, and the gland then returns to a normal condition even though treatments are continued, as is the case with the administration of anterior pituitary gland extracts. He suggests that one of the reasons for the return to normal conditions may be the increase in the amount of circulating thyroid hormone. He also suggests that the neutralizing substances may arise from a protein from which the thyrotropic hormone has not been separated. It may be significant that the hypophyseal extracts which have been used have been prepared from animals of one species—the ox—and that these extracts are not protein free. There is thus the possibility that the cessation of stimulation and subsequent regression is due to a linkage of the hormone to proteins with the consequent production of antibodies which might not be produced by crystalline hormones. No one has as yet reported whether the action of an extract from donors of one species, such as the hog, sheep or horse, would be prevented by the previous injection of a similar extract from another species. The hypothesis of antihormone production is interesting, but it must be attacked from many angles before the transitory effects from the injection of extracts can be definitely referred to a true antihormone production.

SPECIES AND SEX VARIABILITY

Studies on the pituitary have brought out that there is a species and sex variability in the pituitary content of at least certain of the pituitary hormones and also

that there is a species variability in response to these hormones. This variability is of importance both in the selection of donors of pituitary glands from which to prepare extracts and in the selection of recipients used in the testing of the extracts. The pituitaries of beef appear to be richer in growth hormone than those of sheep. The reverse is the case in the gonad-stimulating hormones as attested by the general use of sheep pituitaries in the preparation of gonadotropic preparations. The pituitaries of horses (in pregnancy at least¹) are richer in gonadotropic principle than those of sheep. The human pituitary is especially rich in the gonadotropic principle.⁵⁴ The pituitaries of fowls, on the other hand, are extremely low in content of gonad-stimulating hormone, as shown by the rabbit ovulation test.

A sex difference in the pituitary content of gonadotropic hormone has been found in adults of all species thus far tested, the pituitaries of males being more potent than those of females. Clark⁵⁵ has found that this does not hold for prepuberal ages in rats, in which the pituitary of females is more potent than that of males. Although no explanation is available for the species difference in pituitary potency, the sex difference, from the work of Clark, can be explained in part at least by the suppressing action of the gonad hormones on the pituitary, for in rats the hormone of the male gonad is secreted at an earlier age than is that of the female. When the secretion of these hormones is prevented by castration at birth, the pituitaries of the two sexes are equal in potency during the age periods covered by Clark's experiments (puberal and prepuberal ages). It would be of interest to determine whether sex differences in the pituitary content of gonad-stimulating hormone in the adult are entirely referable to a differential secretory rate of the gonads and a consequent differential suppression of the pituitary.

A species difference in sensitivity to injected extracts is established. Evans and his associates¹ have shown that, whereas one strain of dogs, the dachshund, gives a marked response to injections of growth hormone, another strain, the shepherd, fails to give any response whatever to comparable dosages. The refractoriness of the thyroid of rats as regards a structural response to thyrotropic hormone has been the cause of much lost labor in testing for this principle. The sensitivity of the thyroids of fowls, ducks, rabbits and guinea-pigs, on the other hand, make these forms of value in tests for this factor. The situation as regards the gonadotropic hormones is even more complex for there is both a quantitative and a qualitative difference in the responses of different species. Mice are much more sensitive to the follicle-stimulating fraction than are rats, whereas rats give a greater response to pregnancy urine extract than do mice, although they are much heavier. Qualitative differences in the response of different species to gonadotropic hormones may be very pronounced. The best example to my knowledge is the difference in response of rats or mice and of monkeys to injections of the gonadotropic principle in pregnancy urine. The ovaries of the former, as demonstrated by the usual Aschheim-Zondek test, show follicle growth as well as hemorrhagic follicles and corpora formation.

The ovaries of monkeys injected with this principle, on the other hand, show no follicle growth whatever.⁵⁷ There is a hyalinization of the monkey ovaries, and, in contrast to the reaction in rats and mice, no stimulation of secretion of estrogenic substance occurs. The reason for the differences in ovarian responses is unknown. It may be due to the end organ (ovary) or to the amount of circulating pituitary hormone, the phenomenon of "activation"⁵⁸ or "augmentation" (Leonard,⁵⁴ Fevold, Hisaw and their associates⁵⁹) may play a part. Human ovaries, judging from the work of Geist,⁵⁸ appear to react as those of monkeys to injection of pregnancy urine extract. As shown in another section, the ovaries of all these species react in a nearly identical way to pituitary follicle-stimulating hormone.

It is evident that the response elicited by injections of the pituitary or any other hormone is dependent on at least two factors, namely, the stimulating capacity or potency of the dosage given and the responsive capacity of the receptor tissues or organs. A diminution or increase in either of these factors will alter the effect. In work on the pituitary gland the potency of extracts has been given a more prominent place than has the responsive capacity of the receptor, though current literature indicates that the importance of the latter is being realized more and more. General credence was earlier given to the view so ably sponsored by Keith and others that racial size, for instance, was refractive to the secretory activity of the pituitary. It is not to be denied that the secretory rate of the endocrines may be influenced by heredity and even that this influence may be so profound as to cause an entire failure in the production of a secretion, as in the case of growth hormone in the dwarf mouse.⁶⁰ That this is not the main or even a significant cause of racial skeletal peculiarities, however, is being shown by the very instructive interbreeding of different strains of dogs⁶¹ and by the work of the experimental embryologists on the experimental transplantation of limbs or organs (Harrison⁶¹ and others). In these experiments it has been shown that, under the same endocrine environment, limbs or other structures from two species of different sizes will respond differentially because of their inherited growth capacity.

The response is influenced not only by the genetic constitution but by other factors, prominent among which is the aging process. The importance of the latter is well exemplified by the ovary. It has been shown experimentally that prior to a certain age level the follicles are incapable of responding to injections of the follicle-stimulating hormone, although the follicles may be of considerable size.⁶² From conditions found in women it may be surmised that after a certain degree of aging the reproductive organs lose their

capacity to respond, for, after the menopause, follicle-stimulating hormone may be present in large amounts yet reproductive cycles cease.

It was stated at the beginning of this article that the problem of the physiology of the pituitary gland has become more complex rather than simplified by investigations reported in the last few years. The validity of this statement is attested by the fact that there are now an increased number of hormones the interrelationships of which functionally and chemically have hardly been explored at all and by the fact that there has been shown to be a differential capacity of response in various species and even in the same species at different age levels.

THE HYPOPHYSEAL GONADOTROPIC HORMONES

PHILIP E. SMITH, Ph.D.

Professor of Anatomy, Columbia University College of Physicians and Surgeons

NEW YORK

The discovery in 1926-1927 that the anterior pituitary gland secreted a substance essential to the functioning of the gonads has been followed by many investigations, which have greatly extended the knowledge of the pituitary-gonad interrelationship.

I do not wish to give the impression that important work in this field had not been done prior to 1926-1927. The observations published here and abroad at that time were only a final demonstration of the important role played by the anterior hypophysis in reproduction. More than twenty years ago Cushing and his co-workers¹ and Aschner² had demonstrated that hypophysectomy caused an atrophy of the reproductive system. By partial gonadectomies, parabioses and the like it had also been shown that some extragonadal factor was essential to gonadal function. Evans and Long³ had secured excessive luteinization of the ovaries in normal rats by the injection of anterior lobe extracts. In 1927 restoration of gonadal function after hypophysectomy with hypophyseal implants⁴ and induction of precocious sexual maturity with the same treatment (Aschheim,⁵ Smith,⁶ Smith and Engle⁷) conclusively demonstrated that the anterior lobe maintained and controlled the activity of the ovaries and testes and through them influenced the other reproductive organs.

Although the extracts thus far prepared do not have the desired physiologic purity, evidence gained from their use in the laboratory strongly indicates that two types of preparations can be made. One of these in the terminology of the response in the female, gives follicular stimulation. The other fraction, the purification of which has not progressed as far as the purification of the follicle stimulator, gives luteinization. As regards the sexes, the former stimulates primarily the germ cell line (male germ cells, ova and granulosa)

and is therefore gametokinetic or gametogenic in its action. The latter, the luteinizer, theoretically should and actually appears to act predominantly on the connective tissue derivatives (the theca cells of the ovaries and the interstitial cells of the testis). In addition to this progress on the fractionation of the hypophyseal gonad-stimulating hormones, gonadotropic substances have been discovered in human blood and urine during pregnancy, after ovariectomy and the menopause, in certain tumors of the reproductive organs, and, in smaller amounts, in the blood and urine of men and women during the normal reproductive period. A gonadotropic substance is present in large amounts in the blood serum of mares during approximately the middle third of pregnancy and, in small quantities, in the blood of certain lower forms after castration. Although this paper deals primarily with the pituitary hormones, it will be advisable also to discuss briefly the action of the gonad-stimulating principles in the blood and urine. It seems clear that certain of the latter are actually secreted by the anterior lobe, and, although the origin of others is problematic, nevertheless a statement of their action is of value in a discussion of the gonadotropic hormones known to be of pituitary origin.

"FOLLICLE-STIMULATING" AND "LUTEINIZING" HORMONES OF THE HYPOPHYSIS

Work on the fractionation of the gonad-stimulating factor of the anterior pituitary has been vigorously carried on for a number of years by Fevold, Hisaw and their collaborators.⁸ More recently, Wallen-Lawrence⁹ and Evans and his co-workers¹⁰ have reported extracts secured by other methods of fractionation. Hisaw and Fevold have secured a fraction which in female hypophysectomized rats, in young rabbits, or, with limited treatment, in immature rats, gives pure follicle growth.¹¹ In the latter form, corpus luteum formation will take place after several days of treatment, a result undoubtedly due to the secretion of the animal's own pituitary gland. The effects from the injection of their follicle-stimulating fraction in hypophysectomized females are identical with those secured by the injection of extracts of the urine of postmenopause or ovariectomized women (Leonard and Smith¹²). In normal immature rats or mice this urinary principle gives also follicular growth (Hamburger¹³), which may be followed by corpus luteum formation. In immature monkeys both the anterior hypophyseal follicle-stimulating fraction and the extracts of urine of castration give pure follicular growth.¹⁴ Thus the principle in castrate or menopause urine seems to be identical with the follicle-stimulating fraction prepared from pituitary glands.¹⁵

15 H. C. A. Lassen and E. Brandstrup (Acta obst et gynec. Scandinav 14: 89 1934) report that women castrated surgically by x-rays excrete both a follicle stimulator (prolan A) and a luteinizer (prolan B) the proportions of which vary. In this work normal rodents were used in determining the proportions. Although hypophysectomized rats would seem to be a much more reliable test form nevertheless their observations are significant and call attention to the need of making further analyses.

The gonadotropic principle in pituitaries of horses that have long been castrated also consists largely or entirely of the follicle-stimulating fraction (Hellbaum¹⁶).

A noteworthy feature in treatments of rodents or monkeys with the follicle-stimulating fraction (from castrate urine and probably from the hypophysis also) is the absence of cyst formation in the ovaries, even with large doses (Smith and Engle¹⁷). The injection of unfractionated extracts of the hypophysis (from the sheep) or implants, on the other hand, cause frequently the formation of large cysts in these animals. From these experimental results the clinical use of a purified follicle-stimulating extract will presumably be attended with much less danger of cyst production than will use of unfractionated gonadotropic hypophyseal extracts.

The action of the castrate-urine follicle-stimulating principle in hypophysectomized males is of great interest. The seminiferous epithelium of the atrophied testes of such animals shows a profound response, spermatids and even spermatozoa being produced with a slight or no response of the interstitial tissue, as revealed both by structural studies and by a failure of the accessory reproductive organs to hypertrophy (Smith and Engle¹⁸). Evans and Simpson¹⁰ have recently reported a similar effect from a principle secured by fractionating the hypophysis. Their extract thus also acts as does the principle in castrate urine.

The evidence therefore rather convincingly shows that a fraction can be extracted from the anterior lobe which appears to be physiologically identical with that in castrate urine and which stimulates in both sexes predominately the germ cells (and tissues having the same origin, as the granulosa of the ovarian follicle). This principle therefore could well be designated as a gametokinetic principle.

The present status of a "luteinizing" gonadotropic hormone as I see it is not as definite as that of the gametokinetic fraction.

Fevold and his associates⁸ and Wallen-Lawrence⁹ have reported a fraction from the anterior lobe which, when injected alone, will cause but a slight or no increase in ovarian weight and will produce no luteinization unless large follicles are present. If injected with a "follicle-stimulating" fraction, the follicles that have been stimulated to growth by the latter will then become luteinized. In my opinion, adequate tests have not been reported with this material in hypophysectomized animals in which any confusion due to the secretion of the animal's own hypophysis is eliminated.

In many respects the gonadotropic principle in human pregnancy urine meets most of the requirements that it seems justifiable to postulate for a "luteinizing" principle. This is stated without prejudicing the question of the site of formation of this principle, conclusive data on which are not yet available. Extracts of pregnancy urine, as has been repeatedly demonstrated, will not cause follicle growth when injected into hypophysectomized rats (Selye and his collaborators,¹⁹ Leonard and Smith,²⁰ and others). It produces a

pronounced luteoid change of the theca cells of the follicle and, according to the results of Leonard and Smith, true corpus luteum formation also if follicles of a size sufficient to be acted on are present. When injected subsequent to the follicle stimulation fraction in hypophysectomized female rats it produces luteinization and "augmentation" (see next section). In males, whether normal or hypophysectomized, it produces an extensive interstitial tissue hypertrophy. However, it also stimulates the seminiferous epithelium (Smith and Leonard²¹), an effect which, although repeatedly denied by Collip,²² has been confirmed recently by Evans and his associates²³ and which is supported also by the work of Brosius and Schaefer²⁴ in cases of aspermia in man. Thus action on the seminiferous epithelium may be due to a gametokinetic fraction in pregnancy urine, the action of which is masked in hypophysectomized females by the "luteinizing" fraction. In monkeys in which it seems difficult to secure luteinization the pregnancy urine extracts alone hyalinize the ovary, and such appears to be the case also in women (Geist²⁵). In combinations with hypophyseal gonadotropic extracts it may cause luteinization in monkeys (Engle²⁶), Westman²⁷ reports corpus luteum formation in a woman after the menopause who was given a transfusion of blood from a pregnant woman.

OTHER SUGGESTED PRINCIPLES OF THE ANTERIOR PITUITARY

Mention should be made of two other gonadotropic hormones that some work has suggested.

"Ovulation Hormone"—Mention of the possibility of an ovulation hormone appears not infrequently in the literature, though in my opinion the evidence does not indicate the formation of such a hormone. Although in some nonspontaneously ovulating forms (rabbit, ferret) ovulation can be induced during their extensive periods by injection of most anterior lobe extracts, in other forms the induction of ovulation is accomplished with difficulty. In hypophysectomized rats many follicles can be brought to a mature size only to regress and be replaced by others by the daily administration of a gametokinetic (follicle-stimulating) pituitary extract. Ovulation will not take place apparently until a luteinizing extract is injected. Many failures have resulted in experimental attempts to secure ovulation in monkeys whose follicles have been matured by the injection of a follicle-stimulating extract. Recently this has been achieved by Hisaw and his group, by correctly balancing the amounts of follicle-stimulating and luteinizing extracts that were injected.²⁸ An excessive number of eggs were secured. Ovulation appears not to be due to a specific principle but to the

concurrent action of these two fractions at a correct stage of follicular development.²⁹

"Synergistic" Principle—It has been demonstrated that the concurrent administration of a low dosage of gonad-stimulating fraction and of a pregnancy urine extract gives an ovarian response in rats much greater than would be predicted from the sum of the responses of the two substances acting alone. This has been characterized as "activation" by Evans and as "augmentation" by Hisaw and his co-workers. Its explanation has caused the introduction into the literature by Evans and his associates of the term "synergistic principle" in a way which indicates that it is considered as a separate hormone (Evans and his associates³⁰). It has been demonstrated that "augmentation" with pregnancy urine extracts and anterior pituitary extracts takes place only when the latter contains a gonad-stimulating principle.³¹ It will also take place when two pituitary gonadotropic principles, one causing predominantly luteinization and the other follicle growth, are concurrently injected. The assumption of a separate "synergistic" principle to explain the augmented response seems unnecessary. It seems to be adequately explained by the assumption that the follicle will pass through full development to corpus luteum formation only when acted on by a "luteinizer" in addition to a "follicle stimulator." The former, when acting alone, may give no increase in ovarian weight but, when introduced in the presence of follicles stimulated by the latter, it will cause luteinization, and apparent augmentation will result. Because "augmentation" will occur in the rat, it should not be inferred that it will occur in all other forms.

Pregnancy Mare Serum—Although but a limited space was allocated for this review of the gonadotropic hormones, the review would seem to be incomplete without at least a short discussion of the gonad-stimulating substance discovered by Cole and Hart³² in the serum of pregnant mares during the midperiod of pregnancy. This substance is present in large amounts in the serum. No structural description of the effects of the injection of this have been published, though Evans and his co-workers³³ have reported enormous enlargement of the ovaries from its injection in hypophysectomized female rats. It is pertinent to state that the size of the response is no criterion of the effectiveness of a gonadotropic substance in restoring ovarian function. A normal sized gland that is structurally normal is the desideratum. They have reported that it restores the function of the testes after hypophysectomy. This I can confirm. Both the seminiferous tubules and the

29 It is probably premature and therefore unwise to attempt to correlate these results with the normal cycle. It is tempting to hypothesize on the subject however. If, in the normal cycle the follicle-stimulating hormone causes the growth of the follicle, this then being followed by the secretion of the luteinizing hormone which acts in the second part of the cycle the extra-ovarian factor causing ovulation may well be the balanced action of these two principles in the mid interval (ovulatory) period.

interstitial tissue are stimulated and complete restoration of function results. In hypophysectomized (or normal females) it gives both follicular growth and luteinization, thereby explaining the enormous ovaries that can be secured from its administration. These results in both males and females thus indicate that the pregnant mare serum contains some principle in addition to a follicle stimulator. Recent results of Cole and Hart³⁴ have led them to believe that there are two principles in the serum.

CONCLUSIONS

Work on the gonadotropic substance from the hypophysis and from other sources (from castrate and menopause urine) strongly indicates that the principle commonly designated as the gonad-stimulating principle is composed of two principles. One of these, a gametokinetic (follicle stimulating) principle, has been secured in a fair degree of physiologic purity by fractionation of the anterior hypophysis, and it is also present with little or no contamination with other hormones in the blood and urine after the menopause and ovariectomy. Work with the other principle is somewhat less satisfactory. It appears that the other factor, which may at this time be designated as a "luteinizer" causes luteinization of the ovary. It presumably acts also on the interstitial tissue of the testes. The present indications are that in the therapy of hypogonadism due to a hypophyseal deficiency the administration of one or the other or a proper mixture of these two factors will be required to induce normal gonadal function.

INTERRELATIONSHIPS AMONG URINARY, PITUITARY AND PLACENTAL GONADOTROPIC FACTORS

J. B. COLLIP, M.D.
MONTREAL

The discussion in this article will be confined to the known estrogenic and gonadotropic factors of the pituitary, placenta and urine. A great mass of factual evidence bearing on these active principles has been accumulating within the past few years and indeed is still being added to rapidly month by month. Proved facts must be accepted, but an adequate and totally satisfactory correlation of these facts is quite impossible at this time. I can hope only to present a point of view that seems the most satisfactory explanation of the known facts.

ACTIVE PRINCIPLES

There is a group of estrogenic substances which may be subdivided into those active in castrates and those active only in animals with intact gonads (gonadotropic substances¹). The latter group may be subdivided into two: those of pituitary origin and those of placental origin. Some or all of these are found to occur in pregnancy blood and urine, the placenta, the ovary and the pituitary. In addition to these, there is in the female the luteal hormone—a product of the ovary, and

in the male, the testis hormone, presumably a product of the interstitial cells of the testis. Some conception of the state of confusion in which earlier workers found themselves may be had from the following example. A relatively crude extract of human placenta made by extraction of the fresh material with 50 per cent acetone was found to produce estrus both in castrate rats and in immature rats if administered either by feeding or by injection. The original extract was divided into ether soluble and ether insoluble fractions. The former was effective in the production of estrus either by feeding or by injection, as was the original extract. The ether insoluble fraction, however, had the same properties. It was found that the ether insoluble fraction was more active estrogenically in the intact immature animal than in the adult castrate. The ether insoluble fraction was again divided into two fractions by precipitation with alcohol. Again, both the alcohol soluble and the alcohol insoluble fraction produced estrus when injected into immature rats. The former was effective when fed, but the latter was inert when orally administered. The former was active in large doses in castrates, and the latter was completely ineffective in the absence of the ovaries.

From work of this sort—so confusing at first—with pregnancy urine, blood, placenta and anterior lobe pituitary tissue, carried out by many workers in different laboratories, there emerged facts that allow of classification of the estrogenic substances just mentioned.

ESTROGENIC SUBSTANCES WITHOUT GONADOTROPIC EFFECT

Although different forms of estrogenic substance have been obtained in crystalline form (Thayer, Levin and Doisy,^{1a} Butenandt,² Marrian³ and Browne⁴), it is a fact of special significance that the bulk of estrogenic substance in fresh urine occurs in some organic combination, as yet unknown. The estrogenic factor of the placenta also occurs in combination with some organic substance which is particularly resistant to hydrolysis; it is possible to prepare potent, orally active, estrogenic extracts in which the active principles are alcohol soluble but ether insoluble. The active principle in the water soluble, ether insoluble complex can be split off, for the most part, by acid hydrolysis, and then it will pass readily into an organic solvent such as ether, from which it can be purified. Since the ovary contains only a very small amount of estrogenic principle and as placenta, pregnancy blood and urine are rich in estrogenic material, it has been accepted by most workers that the estrus-inducing factor excreted during pregnancy is of placental origin. Although no positive morphologic effect has been produced on the ovary with purified estrogenic preparations (except by administration of large doses over long periods), it is possible that the ovary may have some action on the placental product in the way of converting it into a more active form (Browne⁴ and Collip, Browne and Thomson⁵).

1 It is necessary that a clear distinction be made between those substances which produce estrus directly (in the absence of the ovaries) which in this series of articles are grouped under the generic title "estrogenic substance" and the gonadotropic principles which produce estrus indirectly by stimulating the production of estrogenic substance by the ovary.—Ed.

GONADOTROPIC PRINCIPLES

There have to be considered here

1 The maturity hormone complex of the anterior lobe

2 The anterior pituitary-like gonadotropic hormone of placenta, pregnancy blood and urine

3 An anterior lobe product found in the urine in certain menopausal cases in the urine of castrates, and occasionally in normal urine

Since the discovery of the gonad-stimulating factor called "prolan" in pregnancy urine by Aschheim and Zondek,⁶ there has been much discussion as to whether this substance is, first, identical with the anterior lobe product and, secondly, if identical, whether the hormone found in the placenta, blood and urine is produced by the anterior pituitary or is produced also by the placenta. It is not within the scope of this review to discuss at length the various points of view relating to these questions, which have been put forward from time to time by various workers in this field. The results of a long series of experiments on the response of hypophysectomized rats to the anterior pituitary-like gonadotropic factor has established quite conclusively that this substance cannot replace the gonadotropic substance of the anterior pituitary. The ovarian response of hypophysectomized rats treated with the pituitary-like factor together with a small amount of anterior lobe extract was the same as that with anterior pituitary maturity substance alone, when administered in adequate dosage.⁸ The recent experiments conducted in our laboratory,⁹ showing that animals resistant to the pituitary-like principle would respond to anterior pituitary gonadotropic extract and that animals resistant to anterior pituitary gonadotropic principle would respond to the pituitary-like factor have given good ground for the view that the latter is not identical with a constituent of pituitary tissue. Since there is ample evidence to show that the maturity hormone of the anterior pituitary is bipartite, it becomes necessary to contrast the action of the placental hormone, which I believe to be a single entity, with each part of the pituitary maturity complex. This, at the present time, can be done only by indirect methods, but such a study shows that the physiologic effects of the pituitary-like hormone and the luteinizing fraction of the anterior pituitary are very similar, whereas there is no such close relationship between the follicle stimulating fraction of the pituitary and the hypophyseal-like principle.

THE INFLUENCE OF THE GONADOTROPIC HORMONES ON THE OVARY

Differentiation among the various gonadotropic principles obtained from the pituitary gland, the placenta and the urine is not very easy at present. It seems

to be well established, however, that the gonadotropic extracts obtainable from the hypophysis have a different physiologic effect from those obtained from pregnancy urine. While the gonadotropic hormone extracted from pituitary tissue produces follicle maturation and corpus luteum formation in the hypophysectomized rat, the anterior pituitary-like hormone extracted from pregnancy urine or human placental tissue produces no follicle maturation and no corpora lutea in the absence of the hypophysis (Collip, Selye and Thomson¹⁰). These experiments have been confirmed by several investigators, and although Leonard and Smith¹¹ reported that in some cases small corpora lutea were observed, they agree with us in that the main action of the pituitary-like fraction in the hypophysectomized female is not the luteinization of the granulosa cells but the transformation of theca cells into so-called theca-lutein cells. Further experiments will have to establish whether the occasional luteinization of an immature follicle by the hypophyseal-like gonadotropic fraction, as observed in Smith's laboratory, is really due to this principle itself or to some accompanying substance.

Similarly, in the male hypophysectomized rat, the only effect of the pituitary-like principle that we could observe was an increase in the size and number of interstitial cells, the seminal epithelium has not been affected.¹² While Smith and Leonard¹³ and also Evans and his collaborators¹⁴ confirmed our statements concerning the increase in interstitial tissue after the administration of the anterior pituitary-like gonadotropic factor in the hypophysectomized rat, their results differ from ours in that they state that administration of the latter leads to sperm cell formation after hypophysectomy.

From all these experiments it is seen that, while the anterior pituitary-like factor acts first of all on the interstitial cells of both ovary and testis, it has only a limited effect, if any, on the seminal epithelium and on the maturing follicle. The gonadotropic hormone obtained from the pituitary itself acts first of all on the follicle leading to maturation and on the seminal epithelium.

The anterior pituitary-like factor, however, as more recent experiments have shown, is not the only gonadotropic substance obtainable from human urine. It has been proved by Zondek¹⁵ and confirmed by numerous other investigators¹⁶ that the urine of castrates and of women in the menopause may contain the gonadotropic principle which Zondek calls "prolan A" and which has the property of stimulating the growth of the graafian follicle without ever transforming it into

a corpus luteum. He also postulates the presence of another gonadotropic factor, "prolan B," which does not stimulate the growth of the follicle at all but transforms granulosa cells into corpus luteum cells. Both these substances would be present in pregnancy urine, while the urine of castrates would contain only "prolan A." Although no gonadotropic hormones can be demonstrated with direct methods in the placenta of rodents, there is some evidence for the presence of a factor, in the pregnant rat and mouse, that inhibits the involution of the corpus luteum of gestation even after the hypophysis is removed.¹⁷ Even the mere mechanical distention of the uterus retards the involution of the pregnancy corpora.¹⁸

The differentiation of these gonadotropic principles is extremely difficult because the pituitary of the experimental animal secretes other hormones, which also influence the ovary. It is absolutely essential, therefore, to use hypophysectomized animals for this type of study.

Experiments on hypophysectomized rats have shown that extracts prepared from castrate urine will lead to follicle maturation in the female and to proliferation of the seminal epithelium and sperm cell production in the male (Leonard and Smith¹⁹). These extracts have no marked effect on the interstitial cells of the ovary or testis.

I should like to outline our conclusions regarding the mechanism of action and the nature of these hormones on the basis of the observations that one may consider as being really well established at the present time. In order to eliminate repetition, I shall not review here the literature concerning the physiology of the gonadotropic hormones, since this will be done by Smith in another paper of this series. The reader is referred to this article, where he will find accounts of the valuable contributions of Lipschutz, Hisaw, Swezy and their collaborators.

The development of the graafian follicle and its transformation into a corpus luteum may be divided into three different periods.^{19a} The first stages of development are found in the ovary of rats between the first and the eighteenth day of life. At this period the granulosa cells do not respond to any known gonadotropic hormone, and the only effect that one can see after the administration of the anterior pituitary-like gonadotropic factor is the transformation of theca cells into theca-lutein cells,²⁰ while the pituitary gonad stimulating principle does not seem to have any effect at all. The nonresponsiveness of such immature ovaries to gonadotropic hormones lies in the ovary itself and not in its hormone environment, because these ovaries will not form mature follicles and corpora lutea even if they are transplanted into adult female castrates.

The second stages of development are found in the ovaries of rats after the eighteenth day of life, and in the ovaries of hypophysectomized animals. Up to this stage of maturation no pituitary hormones are needed. The experiments of Swezy²¹ have shown that ovogenesis is not impaired after hypophysectomy, and since mitotic figures have frequently been found in the granulosa of hypophysectomized rats I feel that the maturation of the granulosa must also be independent of the pituitary hormones up to a certain stage in the development of the follicle. In this second stage the follicle is able to respond to the pituitary follicle-stimulating hormone but not to the anterior pituitary-like gonadotropic factor. If the latter is administered to hypophysectomized animals, only thecal luteinization will take place. If it is administered to the immature animal (around the eighteenth day of age) the follicles of which are also in this stage of development, the same preparation will produce follicle maturation with the subsequent luteinization of the granulosa only because the experimental animal's own pituitary is able to participate in the stimulation of the ovary.²²

The third stages of development are found in the ovaries of animals in full estrus or of hypophysectomized animals after administration of follicle stimulating hormone as obtained from castrate urine or pituitary tissue. This is the stage of full follicular development. At this time, and only at this time, the pituitary-like gonadotropic principle has a direct effect on the granulosa cells, which it is able to transform into corpus luteum cells.

This explains why the hypophyseal-like factor may lead to the formation of a true corpus luteum if injected into a rabbit immediately after hypophysectomy, since in this species fully mature follicles are almost continuously present in the ovary. It further explains why the injection of this substance into guinea-pigs does not lead to the formation of corpora lutea except in the presence of large follicles. Since this species responds to the pituitary-like principle in a manner similar to that of the hypophysectomized rat or rabbit, one may assume that the hypophysis of the guinea-pig does not participate with the injected anterior pituitary-like substance in follicular stimulation. This interpretation would also make Engle's²³ experiments on monkeys more comprehensible. The monkey seems to react very much like the guinea-pig in that here again the pituitary-like factor produces luteinization only after the follicle has responded to hypophyseal stimulation.

It seems necessary at the present time to postulate two hypophyseal gonadotropic hormones, one follicle stimulating and one that luteinizes the theca and the mature granulosa while it has no effect on the immature granulosa cells. The so-called prolan A of menopausal urine appears to consist chiefly of the former, or at least to resemble it closely, whereas the placental hormone of pregnancy urine ("prolan A" plus "prolan B" of Zondek's original terminology) is more comparable, in its biologic relations to the luteinizing fraction.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—ED

THERAPY OF VARICOSE VEINS AND ULCERS

If there is a retrograde blood current in the varicose veins when the patient is in the upright posture, the tissues whose blood should be drained by these veins are supplied by venous instead of arterial blood. Even if the current is not actually retrograde, it becomes so sluggish as to amount to almost the same thing. This accounts for the difficulty of healing varicose ulcer and varicose eczema until the venous stagnation or reversal in capillary flow, as the case may be, has been corrected. This may be done by one of four methods or a combination of these: (1) rest and elevation, (2) supporting bandages, (3) sclerosing injections, (4) surgical ligation of the long saphenous vein.

REST AND ELEVATION

Prolonged bed treatment with elevation of the affected limb to 45 degrees or higher so as to reestablish the centripetal direction of the blood current in the varicose veins is no longer practiced, for the results of this treatment were merely temporary and, as soon as the patient became ambulatory, the ulcers or dermatitis returned.

A person afflicted with varicose veins should keep the legs elevated whenever possible and avoid prolonged standing, which is much worse than is walking, as the pumping action of the muscles favors return flow in the deep veins.

If the patient will not or cannot employ any other treatment, it is quite advantageous for him to sleep with the feet raised about 7 inches above the level of the pelvis (the elevation produced by means of a skeleton wooden wedge placed under the mattress or, more simply, by raising the foot end of the bed). If there is a tendency to edema at bedtime, a mid-day siesta in the same posture should be insisted on.

SUPPORTING BANDAGES

Supporting bandages act chiefly by making the valves of the damaged veins more nearly adequate.

(a) *Elastic Stockings*—The constant wearing, when the patient is up and about, of an elastic stocking or, what is less expensive, a "crape" bandage, is a necessary prophylactic to trouble for all those afflicted with or prone to the development of varicose veins, for example, in pregnancy. The bandage should be applied each morning before rising, even before the leg is put out of bed and while the affected limb still has the advantage of the overnight relief of fluid stagnation, and it should not be taken off until the patient goes to bed for the night. It must be worn regularly. These bandages should extend from the metatarsal region to at least half way up the thigh, leaving the front of the

knee free. It should be made in two parts, one reaching from the toes to just below the knee, the other from the knee to the middle of the thigh. A one-piece stocking is liable to interfere with the movements of the limb and to constrict the circulation about the knee. An intrinsic disadvantage of the elastic stocking, even if it fits well at first, is that it soon becomes worthless either from loss of elasticity or from change in the size or shape of the limb.

(b) *The Elastic Crape Roller Bandage*—This bandage, 4 inches wide (e.g., the "Ace"), has the advantage not only of being less expensive but also of always fitting if properly applied and being washable without losing elasticity, provided the cotton fibers when wet are not stretched, as by wringing or by hanging up to dry.

(c) *Elastic Adhesive Bandage*—This application has revolutionized the treatment of varicose ulcer. The principle underlying this method, enunciated by A. Dickson Wright in 1930, is to apply elastic adhesive plaster strapping with sufficient tension to abolish the circulation in the varicose veins. The patient is kept ambulant and the ulcer is dressed in nothing but its own discharge. If the ulcer is large and the edema considerable, longitudinal strips of adhesive plaster are placed on both sides up the leg to prevent the cutting of grooves in the edematous leg and to keep the bandage from slipping out of position on the surface of the ulcer, which is too moist for the bandage to adhere to. This precaution is not necessary when the ulcer is small or the edema moderate. The elastic adhesive plaster (such as "elastoplast") is wound as firmly and evenly as possible, overlapping each turn of the bandage one half of its width by the ensuing turn. When the edema is great, it may be necessary to use all one's strength in applying the plaster, for looseness of the bandage is the chief cause of failure, and the bandage becomes loose as the edema diminishes. Later applications require less pressure. The patient takes his baths with the plaster in position. He is instructed to wipe off or wash off any discharge that may appear on the surface and to protect the stockings by putting an absorbent gauze dressing over the bandage. The bandage is changed when it has become loose, which may be twice weekly. Later it may be left on for eight days or longer. The bandage is removed, like a cast, by cutting up one side.

Incorporating in the elastic compression bandage a rubber sponge about an inch larger than the ulcerated area (which is first covered with moist sterile dressing so as to favor drainage, the moist sterile dressing being covered with dry sterile dressing, and this with the rubber sponge) has been likened by McPheeters to bringing a "rubber heart" to the aid of the healing, provided the patient walks enough. (McPheeters uses a 4 inch crape ["Ace"] bandage and changes the dressing every other day.) If the ulcer is large and as soon as a healthy granulating surface has been secured, seed implants (see Ulcer Therapy) should be inserted in the granulations and the elastic pressure applied over the grafts, the taking of which it favors. Sclerosing injections may be employed prior to the application of the elastic adhesive bandage and each time it is changed, thereby not only expediting the healing of the ulcer but also preventing its recurrence.

(d) *"Unna's Boot"*—This is especially indicated by varicose eczema, but it is also suitable for chronic leg ulcer, provided there is no edema of the leg. Thus it

is an excellent succedaneum to the elastic adhesive bandage when the tendency to edema has been overcome

For success with this treatment it is essential that the ulcer be free from gross infection (see Ulcer Therapy) and that the circumference of the limb should have been reduced as much as possible. If there is much edema of the leg a day or two in bed with elevation of the limb is necessary. If there is but little edema, the boot should be applied before the patient has been allowed to get out of bed in the morning and after five or ten minutes of extreme elevation of the part. The leg should have been rendered scrupulously clean and be shaved if it is hairy.

Dr Leroy H. Sloan describes a technic of applying Unna's boot that, as compared with the method ordinarily advised, is time and trouble saving. A sufficient quantity of the Soft Zinc Glycerogelatin (N. F.) for use in winter, or of the Firm Zinc Glycerogelatin (N. F.) for use during the summer, is melted, just before it is needed by the application of the least amount of heat necessary. Starch bandages about 2½ inches wide, such as the ophthalmologist employs to cover the eye following operative procedures, are put directly into the melted gelatin preparation, pushed down deep into it and kept there until the bandage is soaked thoroughly. The bandage is then wrapped on the limb just like an ordinary bandage excepting that it is not reversed at any point. Over the last layer of the starch-gelatin paste bandage an ordinary gauze bandage is placed.

The indications for removing the "boot" are soiling and not fitting any longer. Profuse exudate from an ulcer may make it necessary to change the boot twice a week. To cut a "window" over the discharging ulcer is not permissible. Usually the boot may be allowed to remain for several weeks and sometimes even for months. This treatment should not be discontinued soon after healing has occurred for fear of recurrence of the ulcer or the dermatitis, and the boot should be promptly reapplied at the first sign of the reappearance of the lesion.

Definitely to free the patient from the likelihood of these recurrences, the destruction of varicose veins becomes necessary and sclerosing injections have made it possible to do this, in the majority of cases, without the necessity of hospitalization.

3 Sclerosing Injections—Before destroying varicose veins, it is important for the physician to ascertain that they are superfluous. A person whose deep veins are thrombosed requires the superficial venous circulation, even if it is varicose, to carry the blood away from the limb. A history of previous phlebitis of the leg suggests deep vein thrombosis as a probability which can be converted into a certainty by the Perthes test. By means of a flannel bandage one occludes the superficial veins and has the patient walk for an hour and return. Pain, discoloration and swelling of the foot indicate that the case is not suitable for any form of vein destruction and that the best that can be done for the patient is to employ, along with rest and elevation, one of the supporting bandages applied as tightly as is comfortable.

No one, of course, would undertake injection treatment of veins in the presence of fresh phlebitis. It is

also important to recognize residual infection in veins before undertaking the injection treatment, as this would activate it into an acute phlebitis (q. v.). In addition to a history of preceding phlebitis, tender thickened veins and palpable phleboliths as well as a rise in the temperature of the skin overlying such veins should suggest application of one of three provocative procedures (Geza de Takats, 1932). 1. Roentgen irradiation with 150 roentgens applied with 140 kilovolts, 0.25 mm of copper and 1 mm of aluminum to both legs, which is followed by rise in skin temperature if infection is present. 2. Diathermy applied for five minutes over the suspected area, which gives a rise in skin temperature the next day, as compared with the other leg also treated. 3. Puncture of the veins without injection. If such infection is present, foreign protein therapy and a supporting bandage, together with removal of foci of infection may render the provocative tests negative several months later, whereupon injection treatment may be employed.

The presence of infection anywhere else in the system such as acute catarrh of the upper respiratory tract, and septic tonsils or teeth, contraindicates these sclerosing injections. So does advanced age or the presence of severe systemic disease, such as diabetes mellitus, nephritis or obstructive heart or lung disease.

PRESCRIPTION 1—Quinine and Urethane Solution

R Quinine hydrochloride	0.4 Gm.
Ethyl carbamate	0.2 Gm.
Distilled water	3.0 cc.
Sterilize by boiling and dispense in ampule. Inject 2 cc. at an average	

PRESCRIPTION 2—Concentrated Salt Solution

R Sodium chloride	2.0 Gm.
Distilled water	10.0 cc.
Sterilize by boiling and dispense in ampule. Inject from 5 to 10 cc. according to the size of the varix	

Bernstein's classification of the Trendelenburg tests and their correlation with pathologic conditions may be of value in developing the indications for and the prognosis of the injection treatment. In performing the Trendelenburg test, the veins of the leg are emptied by elevating the limb and by gently stroking the veins toward the femoral ring. The hand then makes pressure at the fossa ovalis and the patient is asked to stand. Normal filling from the periphery distends the veins moderately in about a minute even while the pressure is applied. The presence of valvular insufficiency in the long saphenous vein causes, on removal of the hand, the nonsupported column of blood to fill all the varices rapidly from above downward. This is spoken of as the "Trendelenburg positive" (T+) reaction. If incompetent valves are present in the veins connecting the deep and superficial venous system, rapid filling (within ten to twenty seconds) of the varices occurs even while pressure is being maintained over the fossa valves. This is the "Trendelenburg negative" (T-) reaction. A combination of the two conditions might be spoken of as a "double Trendelenburg" (T±). If there are no valvular defects but merely sacculated veins, Bernstein calls this condition a "Trendelenburg nil" (T0). It is in the last mentioned that best and promptest results are secured from the injection treatment. A positive Trendelenburg reaction indicates ligation of the long saphenous vein before injections are started, otherwise recanalization of the thrombus

is likely to occur within a few months. Such ligation is also indicated when there is a double Trendelenburg reaction. But in this case as well as when there is a Trendelenburg negative reaction a great many injections will be required and these may not have a lasting effect.

Among the numerous competing injection fluids, the solution of Quinine and Urethane (prescription 1) is the outstanding one. It is only when the patient has an idiosyncrasy against quinine or the varices are extremely large that from 5 to 10 cc of a concentrated solution of Sodium Chloride (prescription 2) is employed. This solution has the disadvantage of causing a severe cramp in the muscles of the leg.

During the performance of the injection it is perhaps most convenient to have the patient stand on a bench about 18 inches above the floor. After proper cleansing, the injection is made, beginning generally with the lowest varicosity and working upward. An exception to this rule occurs in cases of ulcer in which the varices above the knee—but not much higher than a hand's breadth above—are injected until the ulcer has been healed. Then injections should be employed to obliterate the varicosities in the leg, otherwise the ulceration is liable to recur.

The vein does not need to be emptied prior to injection. There is no necessity for any apparatus to segregate a portion of the vein. All the equipment required is a syringe and a 22 to 26 gage needle with a short bevel. A sterile gauze pad held in place by adhesive plaster is the final dressing. Should paravenous injection occur, the syringe should be disconnected at once from the needle and the tissue blown up through the needle with sterile fluid, preferably 1 per cent solution of procaine in 5 to 10 cc amounts, which it is always well to have at hand when one gives these injections.

4 Surgery—Surgical procedures are at present confined to the ligation of the long saphenous veins in those cases in which its valves are incompetent, and this is best done before the injection treatment is commenced to prevent recanalization of the thrombus.

Operation as suggested by Nelson J. Howard is done as follows. If the saphenous vein is not visible in the upper part of the thigh, it is traced by palpation of the impulse transmitted on percussion. Under scrupulous asepsis and local infiltration anesthesia, the internal saphenous vein is exposed by a transverse incision at the junction of the upper and middle thirds of the thigh. Without unnecessary trauma, the vein is freed from surrounding areolar tissue. Medium silk ligatures are applied 1 inch apart. After they are tied, the ligatures are left long to serve as traction sutures after the vein has been cut between them. To make certain that the ligature may not blow off under exertion, the proximal stump is then transfixed and tied distally to the ligature, trauma of the proximal stump from forceps and other causes being carefully avoided. Then holding the distal stump of the vein taut by means of the long ligature, one injects in a centrifugal direction from 10 to 20 cc of 20 per cent solution of Sodium Chloride. After this the vein is again tied to prevent escape of the hypertonic solution. The wound is flushed with physiologic solution of Sodium Chloride and closed with interrupted sutures, and a sterile dressing is applied. The patient may go home and work even on

the day of the operation but should return for frequent postoperative inspection of the wound. Skin sutures are removed in a week.

5 Causal Therapy—It is, of course, understood that any discoverable etiologic factor for the varicosities is to be corrected. This applies most especially to constipation and to pelvic tumors. Rest, elevation, and supporting bandages (indications 1 and 2) should be resorted to as a routine during pregnancy to protect women as far as possible against these blemishes. Persons with a tendency to varicosities of the legs must be enjoined against wearing garters or clothing that constricts the abdomen. Excessive fatigue and especially prolonged standing must be avoided. If standing is unavoidable, one should practice as often as possible (from ten to fifteen times daily) deep breathing and foot rolling as well as leg and thigh flexion and extension exercises (such as in bicycling). The presence of a low metabolic rate, suggesting a tendency to myxedema, should be met by thyroid administration. A reducing diet might be required in an obese individual, dietary control and, if necessary, insulin in the diabetic patient, or hematonic therapy in the anemic person.

6 Systemic Therapy—Even though true syphilitic or mycotic ulcers have an essentially different pathology and symptomatology, it is decidedly possible for syphilitic infection or mycotic invasion to delay the healing of leg ulcers or make it impossible, just as vein flow reversal or stagnation may make a syphilitic or mycotic ulcer incurable, unless the varicosities are properly dealt with. Hence the therapy of syphilis (q v) or of the mycoses (q v) needs to be associated when there is coincidence of these conditions.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS Howard A. Carter, Secretary

SONOTONE HEARING AID ACCEPTABLE

This device is manufactured by the Sonotone Corporation of New York City. The outfit consists of a transmitter, booster, ear or bone conduction receiver, and a battery. The principle of operation of the Sonotone does not differ greatly from a simple telephone hook-up. The sound waves are picked up by the microphone, amplified by the booster, and transmitted to the hearing organs of the ear by the bone conduction unit, the oscillator, or through air by the air conduction unit, the earpiece.

In the earpiece type, sound waves are converted by the transmitter into the varying electrical currents drawn from the battery and are conveyed to the earpiece, where they create more or less powerful vibrations of the diaphragm in the earpiece, these mechanical vibrations are then reconverted into sound waves. When the earpiece is placed in or on the outer ear, an air cushion is created between the earpiece and the membrana tympani or drum membrane, chiefly in the canal of the outer ear. The reconverted sound waves of the earpiece are conveyed through this air cushion to the drum membrane and there are again converted into mechanical vibrations, which then are conveyed from the drum membrane to the chain of auditory organs of the middle and subsequently of the inner ear.

In the bone conduction hearing aid, sound waves are converted by the transmitter into electromechanical vibrations, which also bring about variations of electric current drawn from the battery, and these varying electric currents are con-

veyed to the oscillator, where they create relatively greater varying mechanical vibrations. The oscillator, quite unlike the earpiece, does not reconvert these mechanical vibrations into sound waves. Instead, it conveys these mechanical vibrations, as such, to the bones of the head and from there directly to the auditory organs.

One unit was tried out in actual service under the supervision of the consultant of the Council and was found to give satisfactory service. The especially designed dry cell batteries appeared to hold up well, indicating that the current demand was not great. Both the air conduction and bone conduction instruments gave satisfaction, and the selection of the method depends on the conditions of the case. It was found that under some circumstances certain deafened individuals were able to hear better by air conduction, while others heard better by the bone conduction. The selection of the method is left to the discretion of the physician.

The company recommends the use of the special batteries. The reason for this is that the dry cells are manufactured for heavy duty and are different in construction from the ordinary flashlight batteries. Flashlight batteries are designed for long shelf life at the expense of other valuable features. It follows, therefore, that the hearing-aid batteries should give good service if they are not permitted to stand on the shelf more than six months.

In view of the results of the investigation the Sonotone Hearing Aid is included in the Council's list of accepted devices.

ALOE DOUBLE THERAPY LAMP ACCEPTABLE

The A. S. Aloe Company, St. Louis, is the manufacturer of this therapeutic lamp. The unit is mounted on a stand and may be conveniently moved about, and the reflector mounted on a cross arm, is adjustable to any position. The arc is protected by a screen. This unit is called a double therapy carbon arc ultraviolet lamp, because it is possible to make use of the various kinds of carbon for example the A Sunshine Carbon, the C therapeutic carbons and the K carbons. The physician may select the carbon that gives the radiation which he desires.

Aloe Double Therapy
Lamp

It combines in one unit a carbon arc and a ring type infra-red generator. The unit consists principally of a resistance unit, a single carbon arc automatic in adjustment, and a 1,000 watt infra-red generator. The carbons are 8 mm by 6 inches and the lamp draws 15 amperes across the arc.

The mechanism of the unit is so arranged that either the carbon arc or the infra-red burner may be used independently of the other or the two units may be used simultaneously. The lamp may be used with direct or alternating current without further adjustment.

At a distance of 24 inches the carbon arc will produce a "mild sunburn" reaction in three minutes, using a therapeutic C carbon, or within forty-five seconds at a distance of 10 inches, "with visible reddening of the skin several hours later and subsequent granular exfoliation."

The carbon holders are operated entirely outside the bowl of the lamp, thus facilitating their replacement while the lamp is in operation. An automatic blowout prevents the destruction of carbon holders.

The 14 inch polished aluminum hood is universally adjustable to any required position and is provided with a heavy and rigid protective screen. The base is so designed that the extended weight of the bowl cannot tip the lamp over.

This lamp was investigated for the Council and the claims made for it were substantiated. The Double Therapy Lamp, therefore is included in the Council's list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

DIPHTHERIA TOXOID (See New and Nonofficial Remedies, 1934, p. 390)

The National Drug Co., Philadelphia

Diphtheria Toxoid—(See New and Nonofficial Remedies, 1934 p. 392)

For determining sensitivity to diphtheria toxoid the product is supplied in the form of a 1:20 dilution. The test dose is 0.1 cc. injected intradermally. Supplied in packages of five and fifty tests.

DIPHTHERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1934, p. 404)

Lederle Laboratories, Inc., Pearl River, N. Y.

Diphtheria Toxin for Schick Test in Peptone Solution—(See New and Nonofficial Remedies, 1934 p. 405)—Also marketed in packages of one vial containing diluted diphtheria toxin sufficient for fifty tests.

STAPHYLOCOCCUS TOXOID—*Staphylococcus* Ana toxin—Univalent or polyvalent, potent hemolytic and dermonecrotic toxins of *Staphylococcus pyogenes-aureus* altered by the formaldehyde-detoxifying process of Burnet (modified from Ramon). Antigenicity is maintained but toxicity is greatly diminished.

Actions, Uses and Dosage—*Staphylococcus* toxoid has been reported a valuable agent in the prophylaxis and therapy of various staphylococcal pyoderms and localized pyogenic processes due to *Staphylococcus aureus* (boil, carbuncle, furunculosis, acne, and so on). The toxoid is said to be effective in producing active immunity to the dermonecrotic and hemolytic elements of the toxins of *Staphylococcus aureus* and *albus*, irrespective of the individual strain of the infecting organism. The toxoid induces the production of quantitative amounts of staphylococcus antitoxin in the blood serum of immunized persons. Treatment consists in the subcutaneous or intramuscular injection at two to seven day intervals of an amount of toxoid representing the following dermonecrotizing units of toxin (a dermonecrotizing unit is the least amount of toxin which on intradermal injection will produce an erythema with central necrosis at least 5 by 5 mm. in diameter).

First injection	20 units
Second injection	40 units
Third injection	60 units
Fourth injection	80 units
Fifth injection	100 units
Sixth injection	200 units
Seventh injection	400 units
Eighth injection	600 units
Ninth injection	800 units
Tenth injection	1,000 units

Following the completion of the tenth injection subsequent treatment, if necessary, may be maintained at that dosage or increased as the progress of the individual case may indicate.

Lederle Laboratories, Inc., Pearl River, N. Y.

Staphylococcus Toxoid Lederle—Prepared by treating a *staphylococcus* toxin filtrate with 0.3 per cent solution of formaldehyde and storing at 37-38 degrees C. until 0.1 cc. injected intradermally into previously tested rabbits produces no evidence of necrosis. The product is then diluted with 0.25 per cent peptone solution so that two strengths are obtained. Dilution No. 1 containing in each cubic centimeter the toxoid obtained from 100 necrotizing doses of toxin and Dilution No. 2 containing in each cubic centimeter the toxoid obtained from 1,000 necrotizing doses of toxin. The material is then preserved with merthiolate 1:10,000. The usual sterility tests prescribed by the National Institute of Health are made. Safety tests are made by injecting 1 cc. doses into each of two mice. The potency of the original toxin is tested by making serial dilutions and injecting 0.1 cc. of each dilution intracutaneously into susceptible rabbits in order to determine the maximum dilution which will cause necrosis. The least amount of toxin which produces an area of erythema with a central necrosis at least 5 mm. in diameter is taken as one necrotizing dose of toxin.

Staphylococcus Toxoid Lederle is marketed in packages of one 5 cc. vial each cubic centimeter containing the toxoid derived from 100 necrotizing doses of toxin and in packages of one 5 cc. vial each cubic centimeter containing the toxoid derived from 1,000 necrotizing doses of toxin.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
GENERAL DECISION AND REPORT RAYMOND HERTWIG Secretary

FORTIFICATION OF FOODS OTHER THAN DIETARY STAPLES WITH VITAMIN D

There is no convincing evidence from the standpoint of public health of a need for the fortification of foods with vitamin D other than such staple products as milk, cereals and bread, which form the basis of the customary diet of the public throughout the year. It is nutritionally unreasonable to add vitamin D to foods consumed mostly in the summer when sunshine is sufficient for producing this vitamin in the body, or to foods consumed irregularly, especially in the fall winter and spring months. An important prerequisite in the choice of food for incorporating vitamin D is that it be consumed regularly and in considerable quantity in the usual diet throughout the year.

Examples of foods not warranting fortification with vitamin D are sausage and ice cream and such accessories as chewing gum.

NOT ACCEPTABLE

PONY BRAND ARTICHOKE CREAM PULP

The Bottled Pure Juice Company, Campbell, Calif., submitted to the Committee on Foods a cooked, pulped, strained artichoke with added citric acid and salt, called "Pony Brand Artichoke Cream Pulp."

Manufacture—Fresh artichoke free of outer leaves, leaf tips and stems, is washed, boiled until tender, pressed to remove excess water, pulped, strained, admixed with a small quantity of citric acid and salt, heated, canned and processed.

Analysis (submitted by manufacturer) —	per cent
Moisture	87.1
Total ash	1.6
Sodium chloride	0.5
Fat (ether extract)	0.7
Protein (N × 6.25)	2.4
Reducing sugars as dextrose before inversion	3.7
Reducing sugars as dextrose after inversion	6.3
Crude fiber	1.0
Carbohydrates other than crude fiber (by difference)	6.3
Titrateable acidity as citric acid	0.9

Calories—0.4 per gram 11 per ounce

Discussion of Product, Name and Label—The label bears the statements

"Artichoke Cream Pulp. This Artichoke Pulp contains no starch nor sugar and consequently is very beneficial to all those with delicate stomachs, those suffering with diabetes and while it is highly nutritive is not fattening."

It is apparently the intention of the company to exploit the article as a "special purpose food," as shown by the label statement "it is very beneficial to all those with delicate stomachs, those suffering with diabetes is not fattening." The product is essentially useless as a "special purpose food" or for the stated uses. It is no more suitable for the low carbohydrate diet than any canned '5 per cent vegetable.' It has no special value for "those with delicate stomachs, those suffering with diabetes" or the obese. The claim implies medicinal properties not possessed. Contrary to the label statement, the product contains a substantial amount of sugar.

The name and label do not correctly or appropriately inform of the nature of the food. The citric acid and salt ingredients should be declared along with the name 'Cream Pulp.' Part of the name incorrectly suggests the presence of cream, a constituent of milk. A proper name for the product is 'Pulped, Strained Artichoke (Added citric acid and salt).'"

Because of its uselessness as a special purpose food and of the deceptive name and label statements this product, therefore cannot be listed as an accepted food of this Committee.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG Secretary

STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED CEREAL WITH ADDED WHOLE MILK, SOY BEAN FLOUR, TRI-CALCIUM PHOSPHATE AND YEAST, SEA- SONED ONLY WITH SALT

Manufacturer—Stokely Brothers & Company, Inc., Indianapolis

Description—Cooked sieved blend of farina, rolled oats, wheat germ, barley flour, whole milk, soy bean flour, yellow corn meal, salt, tri-calcium phosphate and brewers' yeast.

Manufacture—The ingredients in formula proportions are cooked in milk to 88 C, sieved through a monel screen, canned in enamel lined cans, and processed under pressure at 116 C for ninety-five minutes.

Analysis (submitted by manufacturer) —	per cent
Moisture	86.8
Total solids	13.2
Ash	1.2
Sodium chloride	0.5
Fat (ether extract)	1.1
Protein (N × 6.25)	2.6
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	8.0
Calcium (Ca)	0.26
Copper (Cu)	0.0001
Iron (Fe)	0.002
Manganese (Mn)	0.0003
Phosphorus (P)	0.25

Calories—0.5 per gram 14 per ounce

Vitamins—The manufacturing equipment and procedure by excluding air are protective of the vitamin content.

Claims of Manufacturer—This strained cereal cooked in milk is especially prepared for infant feeding, children, convalescents and special diets. Packed in enamel lined cans. Requires only warming for serving.

IRRADIATED VITAMIN D PASTEURIZED MILK

Distributors—Brighton Place Dairy Company, Inc., General Ice Cream Corporation (New Haven Dairy Division), New Haven, Conn.

Description—Bottled pasteurized vitamin D milk irradiated with ultraviolet rays.

Preparation—The milk complies with legal requirements and is pasteurized by the standard holding method. For description of irradiation, see THE JOURNAL Oct. 7 1933, page 1155. The type of equipment used is the Hanovia-National Milk Irradiator.

Vitamins—Clinical investigation shows this milk to be a reliable antirachitic agent if the proper amount is used. Contains 135 U S P X (Revised, 1934) vitamin D units per quart.

Claims of Distributors—Irradiated antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

FREEPORT TIP-TOP BREAD, SLICED

Manufacturer—Freeport Baking Company, Freeport, Ill.

Description—Sliced white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932 p. 817), prepared from flour, water, sucrose, shortening, powdered skim milk (sweetened condensed whole milk used in winter), yeast, sodium chloride, malt extract, gelatinized white corn flour, soya bean flour and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

SATURDAY, FEBRUARY 16, 1935

EFFECT OF DIET IN EXPERIMENTAL AMEBIASIS

The extreme variability in the clinical and pathologic manifestations of intestinal amebiasis has long been puzzling. Many plausible theories have been adduced to explain, for instance, why one person may harbor *Endamoeba histolytica* in the intestinal tract for years, without apparent clinical symptoms and without serious damage to the body tissues, while another may have the mucosa of the colon practically denuded in the space of a few days from the ravages of this protozoon. The alternating periods of clinical quiescence and exacerbation in many patients also confuse the problem. Orthodox immunology appears to offer little in the way of a solution.

Those with wide experience in the treatment of amebiasis, especially in the tropics, find that diet plays a large part in the severity of infection with *Endamoeba histolytica*, persons who have been on a restricted diet, particularly one high in carbohydrate, often have a more virulent infection than those on a full diet or on one low in carbohydrate. But the reasons presented in explanation of this phenomenon have been merely conjectural.

Recently, Faust¹ and Kagy² and their co-workers³ of Tulane University have reported the results of a series of studies on the effect of diet on experimental amebiasis in dogs, these promise to be of the utmost importance in contributing to the understanding of this difficult problem and in improving the methods of treatment of the disease in man. The New Orleans investigators have determined the effects of raw liver, liver extract, other liver fractions, cod liver oil, desiccated hog stomach and canned salmon when added to

the diet of dogs infected by intracecal inoculation⁴ of *Endamoeba histolytica*. Dogs so inoculated develop severe acute amebic enteritis with extensive ulceration of the colon, ordinarily only the trophozoite stage of the parasite can be recovered from the stool.

Feeding raw liver or liver extract in adequate amounts to such dogs causes rapid and definite clinical improvement and healing of the intestinal lesions. The stool tends to become dehydrated and formed, the amebas encyst and may disappear from the feces altogether. Although ordinarily only the active form of the ameba is found in the wall of the intestine, encysted organisms may be seen behind healed surface lesions after liver feeding. The mechanism whereby raw liver or liver extract changes the course of intestinal amebiasis is not known. In part the effect appears to be related to the tendency toward dehydration of the feces, but, as Faust and Kagy² point out, there are undoubtedly other factors involved in this process. Raw liver or liver extract is not amebicidal but amebostatic, in some of the animals under therapy with raw liver, complete eradication of *Endamoeba histolytica* has been noted but this does not occur uniformly. Faust and his co-workers³ found that greater and more rapid improvement took place when the raw liver was finely chopped than when it was ingested whole. Still more rapid improvement occurred if both the liquid and solid fractions of finely chopped liver were introduced intracecally. The active material is apparently destroyed by heating in an autoclave at 17 pounds pressure for twenty minutes, rapid exacerbation of the condition occurred following oral or intracecal administration of liver so treated. Also, after heating at 70 C for thirty minutes to coagulate proteins, the washed solid material was ineffective on oral administration but the liquid fraction produced healing. Cod liver oil also has been found to have a beneficial effect¹.

In contrast to the ameliorative effect of most of the liver products, the oral or intracecal administration of desiccated stomach or the feeding of canned pink salmon caused rapid and severe exacerbation of the disease. However if the desiccated hog stomach was previously subjected to the heat of an autoclave at 17 pounds pressure for twenty minutes, oral or intracecal administration resulted in improvement rather than exacerbation. Or when whole salmon was given intracecally instead of orally, improvement also occurred, but peptic or tryptic digests of the salmon injected into the cecum resulted in serious aggravation of the enteritis.

While the explanation of these important investigations of Faust and his collaborators is not yet clear, their observations are of the greatest importance to an understanding of the processes involved in amebiasis and promise to be of inestimable value in the prevention and treatment of this disease.

THE ANEMIA OF PREMATURE INFANTS

The investigations that have been conducted in the modern "renaissance of hematology," particularly those dealing with the anemias of infancy, have yielded information of interest. The fact has been well established that the hemoglobin level of normal, full-term infants, which is extraordinarily high at birth (from 18 to 20 Gm per hundred cubic centimeters), decreases progressively after birth to a moderately anemic level of approximately 10 Gm per hundred cubic centimeters of blood and thereafter increases slowly during the years of childhood and adolescence to an adult level. Similar but more definite changes occur in the blood of premature infants. The early fall in the hemoglobin level is more rapid and more pronounced than in full-term infants. Indeed it appears that the greater the degree of prematurity, the lower the hemoglobin level reached, values as low as 7 Gm per hundred cubic centimeters being occasionally found. Anemias of this degree must be regarded as pathologic. While it is probable that a low percentage of hemoglobin in itself is not harmful, it may well be indicative of a condition that renders the infant more likely to succumb to infections and other disease processes. Therefore knowledge of the cause and hence of the rational therapy of the anemia of prematurity is of prime importance.

According to current opinion,¹ three main mechanisms may be concerned in the development of the anemia of prematurity: (a) Deficient antenatal storage of iron or perhaps copper or some other essential hematogenic material, in the premature infant this factor might conceivably be exaggerated by the shortened period available for the storage of blood-forming substances; (b) Deficient blood formation due to marrow hypoplasia; (c) Increased blood destruction.

Recent investigations² have yielded further information indicating that a deficient storage of iron, copper and probably other essential material is not primarily responsible for the early anemia of premature infants. Hemoglobin, erythrocytes and reticulocytes were followed in groups of infants of varying degrees of prematurity for as long as three or four months. At different stages of the experiment, iron, copper or liver was administered and the hematologic effects were noted. Iron given during the period of from six to ten weeks after birth had no effect on the proportion of reticulocytes or on the hemoglobin and erythrocyte levels. The usual decrease in these values was unaffected. After the early period of nonreactivity there followed a short "transition" period in which iron elicited a delayed response. After the third month, iron therapy produced a prompt reticulocyte rise and

the usual subsequent increase in pigment and erythrocytes. Similar results were obtained with liver given at the different periods. Copper, in the few cases studied, appeared to have no demonstrable effect.

As a deficient supply of iron, copper and the hematogenic material in liver is apparently not involved in the etiology of the early anemia of prematurity, the other suggested factors become of added interest. There is some evidence that hypoplasia of the erythroid element of the bone marrow, in a strict anatomic sense, is not responsible for the anemia. The fact that, in the investigation cited, a continued reticulosis was observed during the period of the development of the anemia is not indicative of an inactive marrow. On the other hand, certain experiments indicate that increased blood destruction may be responsible for the rapid fall in hemoglobin. The high concentration of bilirubin in the serum of premature infants during the first few weeks after birth and the slightly low osmotic resistance of the erythrocytes are examples of the evidence in favor of this point of view. The present available information, however, does not permit a final statement concerning the relative importance of a lack of blood formation and increased blood destruction. It is possible that both are involved. Further studies of these two factors, as well as others such as growth and hydration effects, should yield information of value in the final elucidation of the cause and proper therapy of the anemia of premature infants.

HOSPITAL MORBIDITY STATISTICS

The need for morbidity statistics approaching in volume and accuracy those for births and deaths is obvious. The practicability of available methods of accomplishing this object has not yet been widely disseminated. Bolduan¹ has recently revived a suggestion made by him in 1913 showing how the vast mass of hospital morbidity may be employed for statistical study with relative ease.

The method that he proposes can be used no matter what system of nomenclature is employed in such hospitals, as he points out, however, the Standard Classified Nomenclature with the ingenious numerical designations devised by Logie would seem to offer a particularly opportune time for such a statistical inquiry. The basis for the system proposed is the "discharge certificate." These certificates would be supplied to all cooperating hospitals, and for each patient discharged a certificate properly filled out would be sent to a central recording bureau. The certificate contains space in sufficiently condensed form for ordinary data concerning sex, age, race, nationality, social condition, occupation and residence, together with a few comments on the patient's admission, stay in and discharge from the hospital, the disease and its complications. The

¹ Bolduan C. F. Hospital Morbidity Statistics. Department of Health of the City of New York, No. 5 April 1913, second printing 1934.

amount of clerical work in filling these certificates would not be large

At the central recording bureau each certificate should be looked over by a trained physician registrar, who would indicate on each certificate the correct designation under the standard nomenclature. The tabulating clerk may then transfer, by means of punch holes, all the information on each certificate to a correspondingly numbered tabulating card. In this way tables of almost infinite variety may be prepared from the information received.

The value of the resulting data would be manifest in numerous ways. Thus, for example, a tabulation of the cases of inguinal hernia might reveal that in one hospital the average length of stay was twelve days, in another this might be eighteen days. If the results obtained were equally good, a change in methods at the second hospital might enable the latter to reduce its hospital stay for cases of this type. Such analysis might also reveal that there were more patients of a certain type in one hospital than in others, and this in turn might indicate facilities that are not readily available in the other hospitals. Important correlations of certain diseases with race, sex, occupation or other factors might also be revealed.

The expense of such an undertaking, according to Bolduan, is composed of two factors: the preparation of tables, and their analysis and publication. After such work had been organized and running for some time, he estimates that the preparation of tables concerning 200,000 cases would probably not exceed \$12,000 per annum, and the printing of an annual report would probably be less than the present total cost of the individual hospital reports. The participating hospitals would have practically no additional expense.

NARCOTIC FARMS—A PUBLIC POLICY

Elsewhere in this issue (on page 574) appear the regulations governing the admission of persons to the federal narcotic farms, the first of which is being established at Lexington, Ky. Addiction to habit-forming drugs is widespread throughout the United States. All classes and groups of the general population are affected by such addiction in one way or another. The geographic distribution of these people corresponds relatively to the geographic distribution and density of the population, occupation, age periods of life, nativity, sex, color, and marital or educational status are not exempting factors. Thus, addiction to narcotic drugs resembles an endemic disease, for it is through and on the people. Based on knowledge available, it is estimated that there are about 100,000 drug addicts in the United States.

Perhaps there is no condition in which man is placed that is fully comparable with that of opium addiction, in which food, shelter, raiment, and all those things

"by which men live" are cheerfully abandoned for the drug of choice. Contact and association with others who are addicted to the use of such drugs stand out as the more prominent and frequent immediate causes of addiction. The removal of addicts from American communities is therefore a step in the direction of preventing further addiction.

The authorization and establishment of facilities for the confinement and treatment of persons addicted to habit-forming drugs bears a direct relationship to policies respecting enforcement of antinarcotic laws and the protection of the American community. Problems in penal and correctional procedure, the uses of narcotic drugs in medical practice, research and the quest for more accurate and fundamental knowledge concerning the nature of drug addiction and related phenomena will be studied to better advantage under the conditions prevailing when the new government institutions begin to function. Moreover, these farms are a response to the instinctive demands ever present in the American people that the sick and afflicted shall be set in the way of strength and hope.

SPECIAL RADIO PROGRAM

Under Association News in this issue, on page 568, is another announcement of a special broadcast by the American Medical Association, which has been arranged through the courtesy of the National Broadcasting Company over a coast to coast network. It is announced also in the advertising section. Physicians are requested to call the attention of their patients to this broadcast and also to emphasize that copies of the speeches will be available after the broadcast to all listeners who send a request to the station to which they are listening, to the National Broadcasting Company at either New York or Chicago, or to the American Medical Association. After the broadcast, physicians are requested to express their opinion of the broadcast direct to Mr. Franklin Dunham, National Broadcasting Company, Radio City, New York.

TORNADOES

The excessive heat and scarcity of rain for months after month during 1934 were such absorbing features of the weather that the small number of tornadoes escaped public attention. The United States witnessed during this unusual season only seventy-six tornadoes, while during the season of 1933 its territory was invaded by 260 tornadoes, and in 1932 by 152. In the last fifteen years, only 1919 had as few tornadoes as did 1934. Perhaps the excessive number of lives lost on account of the heat in 1934 was saved by the scarcity of tornadoes. The sixty-five twisters of 1919 killed 205 people, while the seventy-six of 1934 killed only thirty-two. According to the U. S. weather

bureau,¹ the tornado belt consists of Arkansas, Missouri, Iowa, Illinois, and much of Kansas and Nebraska. Other parts of the country may be visited by them, as were New Orleans, Cleveland and Indianapolis recently. Past performance is no index as to where and when the next one will strike. In 1934 the worst tornado occurred at Maryville, Mo. and in 1933 at Nashville. The worst tornado of 1929 hit Minneapolis. In one day, May 1, 1930, there were thirty-two tornadoes in six different states. A toll in human life is often taken by storms accompanied by less violent winds. Indeed, comparatively mild weather in circuitous and indirect ways probably affects the health of more people than do the few violent storms. Unfortunately, but little significant work has yet been done in this interesting field of research.

Medical Economics

NEW DEVELOPMENTS IN BRITISH PLANS

In an address before the Annual Conference of Secretaries of Constituent State Medical Associations in September 1934, Dr. R. G. Leland² said in discussing a recent report of a committee of the British Medical Association:

The previous paragraph indicates that the choice is now between the extension, development and adjustment of the national insurance system to meet the larger problems of medical service and a salaried state service. Concerning the latter the report says: "There can be no doubt that the great majority of the profession is strongly opposed to this. It would seem to be a fair interpretation of the entire report to say that, because the present system of National Health Insurance has become an accepted and valued part of the national life, now only two alternatives are left for the British Medical Association to consider. One of these is the salaried state service and the other an effort to patch up and coordinate the present system of national health insurance with other forms of medical service."

Events in the brief time since this address was delivered indicate that the predicted action is already in sight in spite of the fact "that a great majority of the profession is strongly opposed to this." A cabled report says that several thousand British physicians have formed a trade union and joined the Trade Union Council (corresponding to the A. F. of L. in the United States). This action is taken in order to be prepared for what is now felt to be the early introduction of a universal system of state medicine with salaried physicians.

Alan Moncrieff,³ London correspondent of the *South African Medical Journal*, gives further information of the progress of this development:

Placebo prescribing is well recognized as a fault of our present panel insurance system, and there are other faults (as well as many virtues) which are less obvious. It is interesting to note, therefore, that at the recent Conference of the Labor Party at Southport, time was found between discussion on foreign policy and home affairs to receive a report on a proposed State Health Service which is not based as many such schemes have in the past been based upon the national health insurance service. In effect the panel system would be abolished and all benefits except cash benefits taken away. The medical service would be supplied by the local municipal authorities to all under a £500 income basis, and such service would be available both in the homes and in hospitals for all voluntary hospitals and institutions would be taken over by agreement by the various municipal bodies. The medical services provided would center round well equipped clinics where all the latest methods of diagnosis and treatment would be available. Panel appointments would gradually be transferred into nonsalable positions in the public health services which would eventually be on a whole time basis. Much of this may sound utopian at present, but there is a lot of good sense in the suggestions and it is important that the profession should be fully aware of the possible developments they may expect under the next Labor Government.

COMPULSORY HEALTH INSURANCE

The Committee on Public Relations of the Medical Society of the State of Pennsylvania, of which Dr. William H. Mayer of Pittsburgh is chairman, has prepared the following release, which has been sent to more than 2,000 industries in that state:

There are concerted efforts on foot to socialize the practice of medicine. Should these succeed, general socialization will be under way.

"The Columbia Broadcasting System is broadcasting each week, on Monday evening over sixty one stations, discussions dealing with socialization of medicine, which are predominantly propaganda in favor of this socializing effort."

"The American Association for Social Security, Inc., Abraham Epstein of New York City, executive secretary, has prepared a proposed health insurance bill for introduction into the 1935 state legislatures."

"This proposed law shall establish a state health insurance bureau and commission and build up a state health insurance fund from three sources: 1.5 per cent employers' payrolls paid by the employer, 3 per cent of the wages of employees (deducted by employers and transmitted to the state fund), and 1.5 per cent of the total payroll of employers appropriated from tax funds."

"Their model bill also proposes to combine cash benefits with medical, hospital and dental care. This means that the employer will pay his large share directly and bear his burden as an already heavy taxpayer."

"The business interests of Europe have already suffered as a result of this scheme, which in England in 1933 cost through parliamentary grants \$24,000,000 and in Germany gave clerical employment to 34,300 persons."

"Business men and industrialists should not willingly promote socialization of business and industry in America. If the practice of medicine is socialized, the entering legislative wedge will have been gained."

"Will you not therefore first urge your legislative representatives to discourage the disrupting activities of the 'American Association for Social Security' which is promoting these socialization schemes through active lobbies, second, use your influence with the Columbia Broadcasting Company to prevent the propaganda for the creation of an expensive bureaucracy ultimately destructive of good medical service."

"The Medical Society of the State of Pennsylvania through its Public Relations Committee will be glad to correspond with you further."

Association News

THE ATLANTIC CITY SESSION

Applications for Space in Scientific Exhibit to Close February 25

Attention is called to the fact that applications for space in the Scientific Exhibit at the Atlantic City Session will close on February 25, after which time all applications received will be put on the waiting list.

The Committee on Scientific Exhibit requires that all applicants fill out the regular application blank. Blanks may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

February 21	Heart Muscles
February 28	Protecting the Heart
March 7	Headache

¹ U. S. Dept. of Agriculture, Cmp. Sheet 866, released Feb. 3, 1935.
² Leland, R. G., Health Insurance in England and Medical Society Plans in the United States, A. M. A. Bull. 29, 126 (Oct.) 1934.
³ London Letter, South African M. J. 8, 860 (Nov. 24) 1934.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

February 19 Health Lessons from George Washington W. W. Bauer M.D.

February 26 Health and Education Morris Fishbein M.D.

March 5 Surgery in Diabetics Leland S. McKittick M.D. who will speak from the National Broadcasting Company's studios in Boston by special arrangement.

Special Coast to Coast Broadcast

The American Medical Association will broadcast on a special program arranged through the courtesy of the National Broadcasting Company over a network of stations, beginning at 6 p. m., eastern standard time, Monday, February 18. The program will include music and three speakers from among physicians in attendance at the Annual Congress on Medical Education and Medical Licensure meeting in Chicago on that day. The speakers will be introduced by Dr. Morris Fishbein. The speakers and their topics are as follows:

Advancement of Medical Education Walter L. Biering M.D.

The Prolongation of Life Ray Lyman Wilbur M.D.

The Battle Against Tuberculosis Kendall Emerson M.D.

ALABAMA

One State Board Examination a Year—In the future, only one examination will be held a year for license to practice medicine in Alabama, in accordance with a decision of the state medical board January 5. Formerly two examinations were held, one in January and one in July, under the new ruling the only examination will begin the last Tuesday in June. Applicants who have been licensed by other states with which Alabama reciprocates may file their applications with the secretary of the board at any time.

ARKANSAS

Bill Introduced—H. 218, to amend the medical practice act proposes to authorize the boards of medical examiners, in their discretion, to license without examination diplomates of the National Board of Medical Examiners.

Society News—Speakers before the Fourth Council District Medical Society at Monticello Dec. 3, 1934, included Drs. Henry T. Smith, McGehee on "Relation of the Physician to Public Health," and William R. Brooksher, Fort Smith "Cooperation of the Physician with Organized Medicine."—At a meeting of the Independence County Medical Society at Batesville, Dec. 10, 1934, Drs. Jesse D. Riley, State Sanatorium, discussed problems of tuberculosis, Van D. McAdams, Cord, burns, and Frank A. Gray, Batesville, pneumonia.

CALIFORNIA

Bills Introduced—S. 98 proposes to make it unlawful, except for licensed physicians and for persons licensed specifically by the state board of health so to do to perform diagnostic tests on cultures or material from persons suffering from infectious or contagious diseases. S. 309 proposes that any person convicted of distributing unlawfully narcotic drugs, who is himself not a narcotic addict, may be punished in addition to the other penalties provided by the act, by from one to twenty lashes at a whipping post. S. 391 proposes to establish a system of compulsory and voluntary health insurance. The bill was introduced only by title, however, and the remainder of the bill is to be inserted by the committee on public health and quarantine, to which this bill has been referred. S. 392 proposes to make it unlawful to conduct a clinical laboratory unless it be under the immediate direction of a licensed clinical laboratory technologist licensed by the state board of health.

The state board of health is to license as a clinical laboratory technologist any licensed practitioner of the healing art who has specialized in general clinical laboratory work, such as bacteriology, serology, biochemistry and parasitology, and other allied subjects for at least three years. It is also to license (1) any other person who for more than eight years has been engaged continuously and actively in the work and direction of a clinical laboratory and (2) any other person who can qualify by written and practical examinations to be given by the board. The provisions of the bill, however, are not to apply to any licensed physician maintaining a laboratory in his own office for use in his own practice. S. 413 prohibits the employment of pharmacists and pharmacy clerks for more than an average of six hours a day, for more than seventy-two hours in any two consecutive weeks, or for more than twelve days in any two consecutive weeks. A. 416, to amend the workmen's compensation act proposes to permit chiropractors to render the "medical" care to injured workmen for which the act makes the employer liable. A. 551 to amend the laws regulating the operation of maternity hospitals, proposes to make it unlawful for any such hospital to offer, as an inducement to a woman to enter therein, to dispose of her child or children for adoption. A. 603, to amend the law relating to county hospitals, proposes to require the admittance of any expectant mother, unable to pay for the necessary care, to any county hospital regardless of her length of residence in the county. A. 761, to amend the retail sales tax act of 1933, proposes to exempt from its provisions the gross receipts from the sale of medicine and medical supplies. A. 890, to amend the provisions of the medical practice act with respect to chiropody, proposes (1) to make the words "chiropody" and "podiatry" synonymous and (2) to define "mechanical treatment," which chiropodists are authorized to employ, as the employment of appliances to the plantar or lateral surfaces of the foot or feet, or of pads or the use of adhesive tape strappings, or any forcible means for the correction or treatment of any deformity of the foot or feet but does not permit the treatment of fractures of the bones of the foot or feet or the application of splints or casts provided, however, that the manufacture, the recommendation or the sale of corrective shoes or appliances for the human feet shall not be considered as mechanical treatment. A. 1037 proposes to make it unlawful for any person to own, possess or operate any x-ray device or x-ray laboratory unless such device or such laboratory is operated under the direct supervision of a person licensed by the state board of health. Apparently only licentiates of the board of medical examiners licensed osteopaths and licensed dentists are to be eligible for licensure by the board of health. Such practitioners are to be permitted to possess and use such devices "as are incident to the treatment of patients by means other than x-ray or r-ray devices."

COLORADO

Special Meeting of House of Delegates—Members of the Colorado State Medical Society were cautioned against advocating policies of legislation not officially sanctioned by the committee on public policy in a resolution adopted at a special meeting of the house of delegates, January 16. The meeting was devoted to a consideration of legislation as it affected the medical profession.

Resolution About Sewage Disposal Plants—The Crowley County Medical Society unanimously adopted a resolution, Dec. 8, 1934, which recommended the construction of sewage disposal plants in communities that dump their sewage into streams used for irrigation. The resolution pointed out that Colorado is rapidly losing its reputation as a health center because of the prevalence of intestinal diseases attributed to the irrigation of vegetables with sewage water.

CONNECTICUT

Bills Introduced—H. 543 proposes to authorize the governor to appoint a commission of five members to investigate the subject of health insurance and to report its findings to the next session of the general assembly. H. 631, to amend the medical practice act, proposes that the Connecticut Medical Society and the Connecticut Homeopathic Medical Society shall file annually with the governor the name of one physician whom each society recommends for membership on the medical examining board (thus denying this privilege, which the law now accords to the Connecticut Eclectic Medical Society). H. 1064 to amend the workmen's compensation act, proposes to permit chiropractors to render the medical care to an injured employee for which an employer must pay.

DELAWARE

Bill Introduced—S 37 proposes to make it the duty of physicians, midwives or other persons in attendance at childbirth to use either a 1 per cent solution of silver nitrate, a 10 per cent solution of argyrol, or a 1 per cent solution of protargol, or their therapeutic equivalent, as a prophylactic against inflammation of the eyes of the new born, and to make a record of the prophylactic used and to endorse the details thereof on every birth certificate

DISTRICT OF COLUMBIA

Dr Ruhland Appointed Health Officer—Dr George C. Ruhland, health commissioner of Syracuse, N. Y. has accepted appointment as health commissioner of the District of Columbia, succeeding Dr William C. Fowler, retired. The appointment was confirmed, February 7. Dr Ruhland graduated in 1904 from the Wisconsin College of Physicians and Surgeons. In 1924 he resigned as health commissioner of Milwaukee to accept the Syracuse appointment.

Medical Bills in Congress—S 1737 introduced by Senator Frazier, North Dakota, proposes to prohibit experiments and operations on living dogs in the District of Columbia for any purpose other than the healing or curing of the dog. S 31 and H R 4996 have been reported to the Senate and House respectively, providing for the issuance of a license to practice the healing art in the District of Columbia to Dr Chester C. Groff (S Rept 75, H Rept 87). H R 3451, introduced (by request) by Representative Norton, New Jersey, proposes to amend the law of the District of Columbia relating to lunacy proceedings.

GEORGIA

Bills Introduced—H 230 proposes to amend those provisions of the medical practice act which require an applicant for a license to be a graduate of a legally incorporated medical college in good standing with the board by permitting graduates of one of the two colleges of medicine now existing in the state of Georgia" also to qualify. H 291 proposes to permit hospitals, without complying with the insurance laws of the state, to "offer to the public hospitalization in consideration of a stipulated amount of money collected weekly or monthly in advance." H 331 proposes to grant to hospitals, treating persons injured through the fault of others, liens on all rights of action, claims, judgments, compromises or settlements accruing to the injured persons because of their injuries.

IDAHO

Bills Introduced—H 70 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what the draftsman of this bill cites as the 'uniform narcotic drug act.' The bill, however, differs from the model uniform narcotic drug act in some important particulars. It omits the provisions in the model bill intended to limit the gross quantity of a habit-forming drug a person can buy in exempt preparations within a period of forty-eight hours. H 72, to supplement the pharmacy practice act, proposes a list of drugs, which it denominates as poisons. The bill proposes to make it unlawful for any one to sell any drug so listed without first ascertaining that the purchaser is aware of the poisonous character of the drug and that it is desired for a lawful purpose, without labeling on the container the word "poison" and the name and place of business of the dispenser. It proposes also to make the sale of such a drug unlawful to a minor under 16 years of age without the written order of an adult, and, in the case of certain drugs, to require that the vendor record in a book kept for that purpose the name of the drug sold, the intended use thereof, the date of delivery, the name and address of the purchaser and the name of the dispenser. The provisions of the bill, however, are not to apply to drugs dispensed in accordance with written prescriptions of licensed physicians, dentists or veterinarians.

ILLINOIS

Bill Introduced—H 191 proposes to require a male applicant for a license to wed to present a certificate from a licensed physician that the applicant is free from venereal disease.

Another Credit Bureau—The Medical Credit Bureau was recently organized by the Peoria City Medical Society to furnish members with the financial rating of patients. Under the plan, 'all worthy individuals will receive medical care as heretofore, but the person or persons having the means but not the desire to remunerate the physicians for services rendered

will be asked to receive medical care and attention from the proper municipal, state or federal agencies created for that purpose."

Chicago

Dr Flexner to Give Pasteur Lecture—Dr Simon Flexner of the Rockefeller Institute for Medical Research, New York, will present the thirtieth Pasteur Lecture of the Institute of Medicine of Chicago at the Chicago Woman's Club, April 26. His subject will be 'Virus Diseases of the Central Nervous System: Their Extent and Mode of Infection.'

Symposium on Tuberculosis—The Chicago Medical Society will devote its meeting, February 20 to a symposium on tuberculosis. The following physicians will participate:

Jay Arthur Myers, professor of medicine and preventive medicine and public health, University of Minnesota Medical School, Minneapolis.
Tuberculosis Among Nurses and Physicians.
Kendall Emerson, managing director, National Tuberculosis Association, New York.
Public Campaign Against Tuberculosis.
Harry J. Corper, director, research laboratories, National Jewish Hospital, Denver.
Recent Research on Tuberculosis.
Benjamin Goldberg, associate professor of medicine, University of Illinois College of Medicine, Carities and Collapse Therapy.

Conference on Occupational Disease—The Illinois Manufacturers' Association sponsored a technical discussion on occupational disease from the medical point of view at the Congress Hotel, January 31. The speakers included the following:

Dr Leroy U. Gardner, director, Saranac Laboratory, Saranac Lake, N. Y.
Pathology of Silicosis.
Donald E. Cummings, assistant director of the laboratory, Etiology, Clinical Findings and Prevention of Silicosis.
Homer L. Sampson, Sc.D., director, x-ray laboratory, Trudeau Sanatorium, Saranac Lake.
Roentgen Findings.

A conference was held in the evening, at which speakers were:

F. Robertson Jones, New York, general manager, Association of Casualty and Surety Executives.
Problems of Compensation in Occupational Diseases.
Peter J. Angsten, chairman, Illinois Industrial Commission.
Occupational Diseases and the Industrial Commission.
Dr Clarence O. Sappington, consulting industrial hygienist.
Some Medicolegal Phases of Occupational Diseases.

IOWA

Bill Introduced—H 78 proposes that before any applicant for a license to practice medicine, osteopathy, osteopathy and surgery, or chiropractic may be examined by his professional board, he must pass an examination to be given by an impartial basic science examining board in anatomy, physiology, chemistry, pathology, bacteriology and hygiene. This board is to consist of five members of the faculties of the state university, the State College of Agriculture and Mechanic Arts, the Iowa State Teachers College and any other university or college accredited by the Iowa State Board of Educational Examiners. All members of the board must be learned in the basic sciences, and no member may be licensed to practice any of the healing arts.

KANSAS

University News—A graduate of the University of Kansas who wishes to remain anonymous has contributed \$60,000 to be used for a children's clinic. Members of the faculty are now working on plans for the new structure.

Bills Introduced—H 275 proposes to authorize Fort Hays Kansas State College to provide local and traveling clinics and adequate psychologic clinical facilities for unusual or abnormal children of school age. H 301 authorizes the formation of community hospital districts and the erection of community hospitals. In the management of such hospitals, no discrimination is to be made against practitioners of any school of medicine or healing recognized by the laws of Kansas and all such legal practitioners are to have equal privileges in treating patients in said hospitals.

Society News—Drs Horace W. Carle and Charles Greenberg, St. Joseph, Mo., presented papers on "Hypoglycemia" and "Transurethral Prostatectomy," respectively, before the Atchison County Medical Society, Dec. 4, 1934, in Atchison. —Dr Harry W. King, Kansas City, addressed the Wyandotte County Medical Society, January 23, on 'Carcinoma of the Sigmoid Colon' and Dr John H. Ogilvie, Kansas City, Mo., presented a case of 'Traumatic Suppurative Lymphadenitis of the Left Inguinal Region with Sinus Formation to the Left Sacro-Iliac Joint.' —At a meeting of the Rush-Ness County Medical Society, recently, Dr Vern L. Pauley, Wichita, discussed transurethral prostatic resection, and Dr Clyde D. Blake, Hays, the function of the state medical society. —Dr Noble P. Sherwood, Lawrence, addressed the Shawnee County Medical Society at Topeka, January 7, on 'Hypersensitiveness and Immunity to Tuberculosis.'

MAINE

Bills Introduced—S 241, to amend the medical practice act, proposes to add to the grounds for which a physician's license may be revoked (1) conviction of any crime involving moral turpitude or of any crime in the practice of his profession, (2) immoral or dishonorable conduct or fraudulent or unprofessional conduct in the practice of his profession, (3) habitual intemperance in the use of liquor or narcotics, (4) use of deceptive misleading, extravagant, improbable or unethical advertising. S 198 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what apparently is the uniform narcotic drug act.

MARYLAND

Bill Introduced—H 70 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what the draftsman of this bill cites as the 'uniform narcotic drug act.' The bill, however, differs from the model uniform narcotic drug act in some important particulars. It omits the provisions in the model bill intended to limit the gross quantity of a habit-forming drug a person can buy in exempt preparations within a period of forty-eight hours.

MASSACHUSETTS

Bill Introduced—H 1267 proposes to grant liens to physicians and hospitals, treating persons injured through the negligence of others, on all claims, rights of action, judgments, compromises or settlements accruing to the injured persons by reason of their injuries.

Portrait of Dr. Warren—A portrait of Dr. John Warren, the first professor appointed in Harvard Medical School Boston, was recently presented to the school in memory of Dr. Henry Lyman, who died June 15, 1934. The presentation was made by Major Gen. Robert U. Patterson, surgeon general U. S. Army, and was accepted by the dean, Dr. David L. Edsall. The portrait, which hangs in the school library, was given by the officers of the former U. S. Army Base Hospital number 5, with which Dr. Lyman served during the World War. Dr. Lyman graduated from Harvard in 1912. Interested particularly in biologic chemistry, he was connected for many years with the Collis P. Huntington Memorial Hospital. With the rank of major he commanded base hospital number 5 part of the time, it was stated, when that unit was in active service as part of the American Expeditionary Forces.

MINNESOTA

Personal—Dr. Benjamin F. Smith, superintendent of the Willmar State Asylum since 1927, was appointed to take charge of the Rochester State Hospital by the Minnesota Board of Control effective January 1, he succeeds the late Dr. Arthur F. Kilbourne.

Dr. Cutler Gives Judd Lecture—Dr. Elliott C. Cutler, Moseley professor of surgery, Harvard University Medical School, will give the second lecture in the annual Judd Lecture-ship in Surgery at the University of Minnesota, Minneapolis, February 19. His subject will be "Total Thyroidectomy for Heart Disease." Dr. Edward Starr Judd, Rochester, who endowed this lecture, graduated from Minnesota in 1902.

The Jackson Lecture—Dr. Logan Clendening, professor of clinical medicine, University of Kansas, will deliver the second Clarence Martin Jackson lecture of the University of Minnesota School of Medicine February 20. His subject will be "The Human Side of Medicine." The lecture was established by Xi chapter of Phi Beta Pi Medical Fraternity in honor of Dr. Jackson, professor of anatomy at Minnesota. The first lecture was given by Dr. Walter L. Bierring, Des Moines, Iowa, President, American Medical Association, on "The Temporal Sequence of Medical Events."

MISSISSIPPI

Premedical Work Required for License—The Mississippi State Board of Health passed a regulation, Dec. 31, 1934, requiring that all applicants who are accepted for examination for medical license in Mississippi must have completed two years' premedical work before entering the study of medicine.

Society News—At the fourth quarterly meeting of the Northeast Mississippi Thirteen Counties Medical Society at Tupelo, Dec. 18, 1934, the speakers were Drs. Douglas D. Baugh, Houston, on "The Recognition of the More Common Mental Disorders," George A. Hendon, Louisville, Ky., "Treatment of Peptic Ulcer by Venoclysis," Felix J. Underwood, Jackson, executive officer, state board of health, "Our Mutual

Interest," and Albert G. Leroy, Booneville, "Eclampsia"—Dr. Douglas D. Baugh, Houston, discussed leukemia before the Pontotoc County Medical Society, Dec. 4, 1934.

MISSOURI

Election of Board Officers—Dr. Timothy S. Bourke, Kansas City, was elected president of the Missouri State Board of Health in Jefferson City, January 21, succeeding Dr. Emmett P. North, St. Louis. Dr. William T. Elam, St. Joseph, was elected vice president, succeeding Dr. Peter T. Bohan, Kansas City, and Dr. Elmer T. McGaugh, Jefferson City, was reelected secretary.

Society News—The department of obstetrics and gynecology of St. Louis University School of Medicine presented the following program before the St. Louis Medical Society, January 22. Drs. Laurence M. Riordan and William D. Collier spoke on "Differential Diagnosis of Right Sided Abdominal Pain" and "Pathology of Myxomatous Placenta," respectively. Case reports were presented by Drs. Paul R. Fletcher on "Hydrocephalic Fetus, with Remarks on Treatment," Percy H. Swahlen, "Myxomatous Placenta," and William H. Vogt, "Advanced Extra-Uterine Pregnancy."

Director of Child Guidance Clinic Appointed—The appointment of Dr. Edmond F. Sassin, assistant in neurology and psychiatry, St. Louis University School of Medicine, St. Louis, as director of the Psychiatric Child Guidance Clinic at St. Louis has been announced. Dr. William L. Nelson, the former director, has held the position since the clinic was founded eleven years ago. It was reported that the change is a part of reorganization plans now under way in the department of public welfare. These plans call for the erection of a psychiatric hospital, of which it is hoped the clinic will eventually be made a unit. Dr. Sassin graduated from St. Louis University School of Medicine in 1927.

MONTANA

Bills Introduced—S 53 to amend the law prohibiting the production, distribution or possession of marijuana, proposes to make a violation of the act a felony punishable by imprisonment in the penitentiary for from one to five years and/or a fine of from \$500 to \$1,000. H 120, to enact a new osteopathic practice act, proposes to define osteopathy as "that system of the healing art or school of medicine which in its theory places chief emphasis as health factors upon the structural integrity and natural immunity of the body and in its practice upon the adjustment of structural irregularities and the normalization of functional activity through manipulation." The bill proposes to authorize the osteopathic examining board to license as an osteopathic surgeon any osteopath who has completed two years of at least nine months each of postgraduate instruction in surgery in a recognized and regularly conducted college, or who presents evidence of having completed a one year postgraduate course of at least nine months in surgery in a recognized college, or an internship in a hospital under such college supervision and a one year course of training of at least nine months as a surgical assistant in a hospital having at least twenty-five beds and equipped for major surgical work. This bill omits the specific prohibition contained in the present law against osteopaths prescribing or using drugs and in its stead purports to authorize an osteopath "to practice his profession as taught in recognized and regularly conducted colleges of osteopathy." Osteopaths who are licensed to practice surgery by the osteopathic board are specifically granted unlimited surgical rights.

NEBRASKA

Bill Introduced—H 263 proposes to make it the duty of every physician to respond to any call to assist in the delivery of a child, when he is the nearest available practitioner. Any practitioner violating the provisions of this bill is to be punishable by a fine of from \$25 to \$200.

NEW HAMPSHIRE

Bills Introduced—H 150 proposes a new workmen's compensation act. Compensation is to be granted for injury or death caused by accident arising out of and in the course of the employment but not for disease or death from disease, unless it is the direct result of an accident, except anthrax, lead poisoning, silicosis or disease due to inhalation of poisonous gases or fumes. During the first four weeks of the injured worker's disability, the employer is to furnish reasonable medical, surgical and hospital services and supplies and other necessary remedial care. In the discretion of the industrial accident board the employer may be required to furnish

such care for a longer period H 275, to amend the pharmacy practice act, proposes (1) to prohibit persons, other than physicians and registered pharmacists, from selling or otherwise distributing articles, substances and compounds commonly used or capable of being used as contraceptives or abortifacients and (2) to make the act applicable to the sale of proprietary medicines containing barbitol or other compounds of the barbituric acid series

NEW JERSEY

Bills Introduced—S 140 proposes to authorize the municipalities that do not maintain municipal hospitals to appropriate not exceeding 01 per cent of the total assessed valuation of real and personal property of such municipality to any hospital located in such municipality, which treats indigent residents without cost A 89 authorizes the state department of health to care for, treat, isolate and maintain indigent disease carriers

Society News—Dr Rosco G Leland, Chicago, director, Bureau of Medical Economics, American Medical Association addressed the Essex County Medical Society Newark, January 10, on "Compulsory Health Insurance as It Affects Members of the Medical Profession"—Dr Harlow Brooks, New York, addressed the Bergen County Medical Society, Hackensack, January 8, on "Diseases of the Liver," and Dr Arcangelo Liva, "Oculist versus Optometrist"—Dr Nathan B Van Etten, New York, made an address before the Hudson County Medical Society, Jersey City, January 2, entitled 'How Shall the Sick Be Adequately Served and How Shall the Servants of the Sick Be Adequately Paid?'—A symposium on rheumatic fever was presented before the Camden County Medical Society Camden, January 8, by Drs Harold K Eynon William T Read Jr, B Franklin Buzby, Harold D Barnshaw and Ernest Reed Hirst—Dr Lewis K Ferguson, Philadelphia, addressed the Gloucester County Medical Society, Pitman, Nov 15, 1934, on varicose veins

NEW YORK

Botulism from Imported Canned Sprats—Three cases of botulism with one death were recently reported from Westchester County The three victims had eaten a can of imported Kiel sprats although they noticed that the can was bulging before it was opened, that gas escaped and that the fish tasted sour One man ate for supper twelve fish, another six and a woman three The illness began the next morning, the man who had eaten most became rapidly worse and died the following morning Necropsy confirmed the diagnosis Botulinus serum was obtained from the state laboratory in New York for the other two patients The man who had eaten six fish was desperately ill for a time it was said, but was improving at the time the report was published The woman never showed serious symptoms The spoiled fish was traced to a pedler who said that he had bought fifteen cans from an importer and sold some to other pedlers A technical charge of homicide was placed against him by the county medical examiner Federal officials embargoed the stock of the importer and the New York City Department of Health was reported to be investigating one pedler known to be operating in the city

Bills Introduced—S 474 and S 718 propose a system of compulsory and voluntary health insurance The benefits proposed consist of cash and all forms of medical and dental services Persons employed at 'other than manual labor receiving wages in excess of \$250 monthly,' farm laborers and persons employed by an employer having less than three employees in personal or domestic services, are excluded from the compulsory insurance of the bill but are entitled to participate in its voluntary insurance S 505 proposes to create in the department of mental hygiene a board of psychiatric examiners to license as qualified psychiatrists all applicants who (1) have been licensed to practice medicine for at least five years and have had five years experience in actual practice, and (2) have had three years' full time practice in the care and treatment of persons suffering from mental diseases or mental defects in certain approved institutions or have devoted five years to a practice confined wholly or substantially to the care and treatment of persons suffering from nervous or mental defects S 589 proposes to create in the education department a state board of electrologists and to regulate the practice of electrolysis Electrolysis is defined by the bill as "the method used for the permanent removal of superfluous hair by means of a controlled electric current introduced into the hair follicle by way of a fine metallic needle which is directed into the hair papilla where a chemical decomposition takes place destroying the life of the hair forever" Licenses are to be issued after examination, to persons who are high school graduates and

have completed a course of training of not less than six months in schools of electrolysis approved by the board A 644, to amend the workmen's compensation act, proposes to make compensable all occupational diseases arising out of and in the course of any employment covered by the act A 765 proposes to make it unlawful for any person not a licensed physician or surgeon, to broadcast any surgical or medical advice

New York City

Annual Art Exhibit—The New York Physicians' Art Club will hold its eighth annual exhibition at the New York Academy of Medicine during the two weeks beginning March 30 Members who pay no dues but a fee for their exhibits, are principally New Yorkers, but any physician may send original art work to the exhibit, it is announced Officers are Drs Howard Lihenthal, president, Winifred Morgan Hartshorn treasurer, and Louis C Schroeder, secretary All communications should be addressed to Dr Schroeder at 50 East Seventy-Second Street.

Council to Coordinate Hospitals—The Hospital Council of New York, representing the five county medical societies, philanthropic and welfare agencies and the city government, was organized by Mayor La Guardia at a meeting, January 18, at the city hall With the increased overcrowding in city institutions and decreased support for private hospitals, the hospital problem has grown acute It will be the council's task to define the city's needs, to explain the situation to the public in the hope of calling out latent resources of private philanthropy and of combining private and public resources in the most effective manner, the mayor said Those who attended the meeting were

New York Academy of Medicine Drs John A Hartwell and Bernard Sachs

Medical Society of the County of Queens, Drs Charles F Miller Corona and Howard W Neil Jamaica

Medical Society of the County of New York Dr Franklin Welker

Medical Society of the County of Kings, Drs John S Read and Alec N Thomson Brooklyn

Richmond County Medical Society Drs Arthur S Driscoll and William C Buntin Staten Island

Bronx County Medical Society Drs Milton J Goodfriend and David J Kaliski

Federation for Support of Jewish Philanthropic Societies, Solomon Lowenstein and Frederick M Stein

Brooklyn Federation of Jewish Charities Joseph J Schwartz and Joseph J Baker

Controller of the City of New York Frank J Taylor and G Harry Lynn

Health Department Drs John L. Rice and Herbert R Edwards

Catholic Charities of New York Rev Joseph S O Connell

Catholic Charities of Brooklyn, Mgr Jerome Reddy and Father Brophy

United Hospital Fund David H McAlpin Pyle and Homer Wickenden

Welfare Council, Charles C. Burlingham, Miss Jane Hoey and Robert P Lane.

Commissioner of Hospitals Dr Sigismund S Goldwater

NORTH CAROLINA

Bills Introduced—S 80 proposes to make it the duty of the parents or guardians of all children born in the state to have them immunized between the ages of 6 and 12 months with diphtheria toxoid H 148 proposes to grant to physicians and hospitals, treating persons injured through the negligence of others, liens on all sums recovered as damages by the injured persons by reason of their injuries

NORTH DAKOTA

Bill Introduced—S 75 proposes to grant to hospitals, supported in whole or in part by private charities and treating persons injured through the negligence of others, liens on all rights of action, claims, judgments, compromises or settlements accruing to the injured persons because of their injuries

OHIO

Society News—Drs Walter M Simpson and Arthur M Culler addressed the Montgomery County Medical Society, Dayton January 4 on 'Progress in Artificial Fever Therapy, Research' and 'Artificial Fever Therapy of Ocular Syphilis,' respectively—Dr Dean D Lewis, Baltimore, addressed the Cincinnati Academy of Medicine January 7, on "Cystic Mastitis Its Cause and Treatment."

Founder's Day Clinics—Ohio State University College of Medicine, Columbus, will present its annual Founder's Day Clinics, March 1-2 Dr Russell H Oppenheimer, dean of Emory University School of Medicine, Atlanta will address the alumni on 'The Doctor's Place in Modern Economic and Social Life,' Saturday morning, March 2 There will be clinics at Children's St Francis and University hospitals and tours of the medical buildings of the university Special fea-

tures will be a session devoted to normal and pathologic reactions of the glands of internal secretion and a symposium on cardiology. In the evening March 1, Dr Edward D Churchill, John Homans professor of surgery, Harvard University Medical School, Boston, will deliver the Alpha Omega Alpha address, on "Lobectomy and Total Pneumonectomy." Dr Russell G Means is chairman of the committee in charge of the reunion. Class luncheons will be held at noon Saturday and fraternity banquets Saturday evening.

OREGON

Bills Introduced.—H 180 proposes to limit the distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of conception and/or venereal diseases, to licensed physicians and to persons licensed to do so by the state board of pharmacy. H 208 proposes to prohibit the distribution of amytal, luminal, veronal, barbitol, acid diethylbarbituric, or any preparation or compound containing any of the foregoing substances, except on the prescription of a licensed physician, dentist or veterinary surgeon.

Bills Passed.—H 107 has passed the house, proposing to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what the draftsman of the bill cites as the "uniform narcotic drug act." This bill, however, differs from the model uniform narcotic drug act in some important particulars. It omits the provisions in the model bill intended to limit the gross quantity of a habit-forming drug a person can buy in exempt preparations within a period of forty-eight hours. S 82, to enact a new pharmacy practice act, has passed the senate. In its present form, this bill seems to prohibit physicians from dispensing drugs, merely permitting them to administer drugs and medicines personally in order to supply the immediate needs of their patients.

PENNSYLVANIA

Hospital Appointments.—Dr Enoch H Adams, Berwick, has been appointed surgeon in chief to the Center County Hospital, Bellefonte. Dr William F Herbst has been chosen chief of the medical department of Allentown Hospital to succeed the late Dr Joseph M Weaver. Dr Joseph F Connor, Meadville, who was recently appointed chief surgeon of the Erie Railroad, has also been made chief surgeon of Spencer Hospital, Meadville.

Bills Introduced.—H 404, to amend the workmen's compensation act, proposes to make compensable any occupational disease acquired in any employment covered by the act. H 417, to amend the workmen's compensation act, proposes to require an employer within thirty days after the beginning of the disability of an employee due to an occupational disease contracted in the course of the employment to report the case to the department of labor and industry. S 78, to amend the workmen's compensation act, proposes to make compensable certain occupational diseases, including poisoning by lead, mercury, phosphorus, arsenic, methanol, carbon bisulphide, naphtha, manganese dioxide, brass, zinc, benzol and nitro- and amido-derivatives of benzol, also compressed air illness, radium or x-ray burns, chrome ulceration, cancer or ulcers resulting from tar, pitch, bitumen, mineral oil or paraffin, and infection or inflammation of the skin resulting from contact with oils, cutting compounds, lubricants, dusts, liquids, fumes, gases or vapors, also anthrax, silicosis and chronic miners' asthma. S 83 and H 413, to amend the workmen's compensation act, propose that the bills of physicians or hospitals, for which the employer is liable under the act, be presented to a referee designated by the workmen's compensation board of the bureau of workmen's compensation of the department of labor and industry. This referee is to award remuneration so far as possible in accordance with a table agreed on by the Medical Society of the State of Pennsylvania and by the Pennsylvania State Hospital Association and approved by the board. H 297 proposes to create a board of chiropody examiners and to regulate the practice of chiropody. H 379, to amend the workmen's compensation act, proposes to extend from thirty days to six months the period following an industrial injury during which the employer must provide medical treatment to an injured employee. The present law limits the employer's liability for such services to \$100. The proposed liability under this bill is unlimited.

Philadelphia

Graduate Seminars.—The group of graduate seminars sponsored by the Philadelphia County Medical Society for February is concerned with recent developments in the biology of growth and development and indications for their use in man. John S Nicholas, Ph.D., associate professor of comparative anatomy

on the Bronson Foundation, Yale University, New Haven, Conn., delivered the first lecture, February 1, on "The Contributions of Experimental Embryology to Problems of Mammary Growth and Development." Others to follow are

Conway Zirkle, Ph.D., associate professor of botany, University of Pennsylvania, Genetics—Mechanisms of Inheritance—the Hereditary Basis of Diseases—Artificial Control of Inheritance.
Ezra Allen, Ph.D., New York, The Nature and Functional Basis of Sex—Experimental Effects of Sex Development and Reversal in Animals as Possible Explanation of Certain Human Sex Problems.
Dr Stanley P. Remann, Lankenau Hospital Research Institute, Application of Some Newly Discovered Effects in Malformation and Tumor Formation in Man and Their Relations to the Subjects Previously Discussed.

Society News.—The College of Physicians of Philadelphia held a dinner, Dec 15, 1934, celebrating the twenty fifth anniversary of the occupancy of the college building. Dr William J Taylor was toastmaster, and speakers were Drs Edward B Krumbhaar, David Riesman, George E de Schweinitz and Alfred Stengel. The college recently adopted a resolution urging the transfer of the Philadelphia Hospital for Mental Diseases at Byberry to the state in order to relieve overcrowding. Speakers at a meeting of the Philadelphia Academy of Surgery, January 14, were Drs J Stewart Rodman and William G Leaman Jr, on "Surgical Risks with Special Reference to the Cardiovascular System." John Enan, "Evaluation of Metabolic Diseases as Surgical Risks", Joshua E Sweet, New York, "How Does a General Surgical Procedure Affect the Physiology of the Lung?" and Leonard G Rowntree, "Evaluation of the Renal Factor in Surgical Risks."—Dr John M Fisher has been elected president of the Physicians' Aid Association of the Philadelphia County Medical Society, and Dr Francis Heed Adler, secretary.

RHODE ISLAND

Society News.—Dr George Blumer, New Haven, Conn., addressed the Providence Medical Association, Dec. 3, 1934, on "Importance of Observation and Induction in Diagnosis, with Some Remarks on Errors in Diagnosis." Among others, Dr Harmon P B Jordan and W Henry Rivard, Ph.D., dean of Rhode Island College of Pharmacy, Providence, addressed the quarterly meeting of the Rhode Island Medical Society, Dec. 6, 1934 on "Current Trends in Pharmaceutical Education."—Drs Meyer Saklad and Eric P Stone, Providence, addressed the Washington County Medical Society, January 9, on advances in anesthesia and on birth control, respectively.

Bills Introduced.—S 52 proposes to grant to physicians nurses and hospitals, treating persons injured through the negligence of others, liens on all judgments, settlements or compromises accruing to the injured persons because of their injuries. H 587 proposes to make it the duty of any person in possession of land on which he believes cannabis sativa to be growing to notify the state narcotic board forthwith of that fact. The narcotic board is then to inspect this property and to destroy any cannabis plants that may be found there. The narcotic board is further to be authorized to make surveys to ascertain the extent to which cannabis sativa or cannabis americana is prevalent in the state.

SOUTH DAKOTA

Immunization Campaign.—Eighteen hundred children were immunized against diphtheria in a campaign initiated and carried out by physicians of Sioux Falls recently. The campaign ran two and a half weeks. Treatments were given in the physicians' offices, free to those who could not pay and at fees ranging from 50 cents to \$4 for those who could. Liberal publicity was obtained for the project through cooperation of civic clubs, schools, churches, radio, newspapers and theaters.

Sioux Valley Meeting.—The annual session of the Sioux Valley Medical Association was held in Sioux Falls, January 22-23, at the Cataract Hotel. Speakers included

Dr Oliver S Ormsby, Chicago, Some Mycotic Infections of the Skin and Contact Dermatitis.
Dr Frederick A Williams, Rochester, Minn, Factors Concerned in the Diagnosis of Heart Disease.
Dr Ralph Hess, Kunstadter, Chicago, Diagnosis and Treatment of Endocrine Disorders of Children.
Dr Herman L Kretschmer, Chicago, Present Day Views on Treatment of Prostatic Obstruction.
Dr Louis A Bnie, Rochester, Minn, Proctologic Problems of the Surgeon and the General Practitioner.
Dr Wallace H Cole, St. Paul, Principles in the Modern Treatment of Fractures and Their Development and Historical Survey.
Dr Edward W Rowe, Lincoln, Neb, Principles of Irradiation.
Dr Joseph C Ohlmacher, Vermillion, Pathology of Cancer.

This society includes physicians of the territory adjacent to the intersection of the states of Iowa, South Dakota, Minnesota and Nebraska.

TENNESSEE

Bill Introduced—H 408 proposes to require each coroner to appoint as a deputy a licensed physician whose duty it shall be to ascertain the cause of death of persons who die without medical attention

TEXAS

Bill Introduced—H 334 proposes to require every insurance company doing business in the state to pay a tax of 0.5 per cent of its gross receipts, to be placed in a fund to be known as "the rural and county health fund"

Texas Forty-Fifth in Health Appropriations—The Texas State Medical Association is cooperating with the state board of health in a campaign for increased appropriations by the legislature for public health work in Texas. The campaign was opened at a meeting in Dallas under the auspices of the state board of health, of which Dr Charles M Rosser, Dallas, is chairman, to awaken public concern and focus opinion on the state's health problems. Dr Samuel E Thompson Kerrville, president of the state medical association, made an address on "The Responsibility of the Medical Profession to Public Health", Dr Holman Taylor, Fort Worth, association secretary, on the interdependent relation of the medical profession and the public, Dr John W Brown, Austin, state health officer, on emergency issues confronting public health in Texas, and Dr Knox E Miller of the U S Public Health Service, the health situation in Texas. Similar meetings have been held in various districts throughout the state in an effort to bring this situation to the attention of the public and thereby to the legislature. It was said that Texas is forty-fifth among the states in its appropriations for public health.

UTAH

Bill Introduced—H 82 proposes to forbid any hospital exempted from taxation from discriminating against practitioners of any school of medicine recognized by the laws of the state and to require such hospitals to grant all such practitioners equal rights in treating patients therein. Patients in such hospitals are to have the absolute right to employ at their own expense physicians of their own choice.

WASHINGTON

Bill Introduced—H 178 proposes to repeal the basic science act and to enact in its stead an emasculated basic science bill. The examining committee in the basic sciences is to consist of one nonsectarian practitioner, one osteopath, one osteopathic surgeon, one chiropractor, and one other practitioner of a system of drugless healing. The questions to be propounded in examinations and the grading of each applicant's answers must be approved by a majority of the committee. The bill proposes also to lower the passing grade from 75 per cent to 60 per cent.

WEST VIRGINIA

Hospital Contract Practice Condemned—The council of the West Virginia Medical Association at a special meeting, January 17, adopted a resolution forbidding any of its members to practice "under the terms of or in connection with any hospital list contract which provides for the care or treatment of industrial injuries" or to be on the staff of or in any way connected with any hospital which is a party to any such list contract. The ruling is to take effect April 17 and after that date the council is to ascertain whether any members are engaging in this kind of practice and recommend to the county societies concerned that these men's membership be terminated immediately. If the county society does not comply with this ruling the charter of the society is to be withdrawn. The council explained that it is believed that physicians wish to abolish this type of practice but that it is difficult for any individual or group to avoid it if others are still engaging in it.

WISCONSIN

Bill Introduced—A 88 proposes to make it unlawful for any representative of a relief agency, any employer or his agent or any insurance company or its agent, to influence or to attempt to influence a sick or injured person to engage any particular physician or surgeon or to change to a suggested physician or surgeon.

Personal—Dr Charles O Lindberg, Edwardsburg, Mich., has been chosen head of the medical staff of the Community Hospital at Graustsburg.—Dr George B Durand, Waupun, was guest of honor at a farewell dinner given recently by Waupun physicians. He has retired from practice in Waupun and plans to leave the city, newspapers reported.

Appointments to State Board—Governor Schmiedeman announced five appointments to the state board of medical examiners, Dec 21, 1934, as follows:

Dr John R Venning, Fort Atkinson, to succeed the late Dr Archibald D Galloway Barron.
Dr Alvin G Koehler, Oshkosh, to succeed Dr Wilbur N Linn Oshkosh.
Dr Charles W Giesen, Superior, to succeed Dr Thomas J Sheehy, Tomah.
Edward C Murphy, D O Eau Claire, to succeed himself.
Dr Bartholomew L McGonigle, Ableman, to succeed Dr Adam J Gates Tigerton.

GENERAL

Changes in Status of Licensure—The State Board of Medical Examiners of Oklahoma has reported the following action:

License of Dr Jasper C Holland, Grove, suspended for five years for violation of the federal narcotic laws, Dec 11, 1934.

The Kansas Medical Board reports the following action:

Dr John F Northrup, Topeka, license revoked Dec 11 1934 for conviction on a felony charge.

The Maine State Board of Registration in Medicine reports the following:

Dr Joseph Abbott Nile, Rumford, Maine, license revoked Nov 13, 1934, he was convicted under the Harrison Narcotic Act for the illegal dispensing of morphine and sending it through the mails.

The Massachusetts Board of Registration in Medicine reports the following:

Dr Sarah Margaret Brown, Boston, license revoked Dec 20, 1934 for deceit in the care of a patient.

Dr Rafael Reyes Garcia, Springfield, license revoked Dec 20 1934, for deceit in the care of a patient.

News of Epidemics—Retreat Mental Hospital, Retreat, Pa., reported 200 cases of grip among its 900 inmates. The Luzerne County Prison was quarantined because of several cases, newspapers reported January 6.—Scarlet fever, which has been epidemic in Milwaukee for many months, caused one parochial school to close in January. The number of cases in the city February 1 was 1,361.—The state health department of Washington reported 249 cases of smallpox in the state from January 1 to 22, Bremerton papers reported 100 cases in and near that city. A large number of cases were also said to have occurred in the vicinity of St Anthony, Idaho.—Illinois is reported to be having the most severe measles epidemic since 1926, the state health officer said January 20 that 1,307 cases were reported in the preceding five days.—A severe respiratory infection is epidemic among Indians on the Navajo reservation about Ganado, Ariz., *Southwestern Medicine* reports. The eighty bed hospital at Ganado Mission is reported to have had 125 patients.—Schools were closed in Trescow, Carbon County, Pa, January 27, because of an outbreak of cerebro-spinal meningitis.

Medical Bills in Congress—*Bills Introduced* S 1615, introduced by Senator Hatch, New Mexico, proposes to prohibit the shipment and transportation in interstate or foreign commerce of cannabis and its derivatives and compounds. S 1737, introduced by Senator Frazier, North Dakota, proposes to prohibit experiments and operations on living dogs in the District of Columbia for any purpose other than the healing or curing of the dog. H R 4462, introduced by Representative Thomason, Texas, proposes that for the purposes of promotion, longevity pay and retirement there shall be credited to officers of the Veterinary Corps, and former officers of the Veterinary Corps now on the retired list, all full time service rendered by them as veterinarians in the Quartermaster Department, Cavalry or Field Artillery. H R 5279, introduced by Representative Underwood, Ohio, proposes to adjust and equalize benefits for veterans and widows and dependents of veterans. H R 5289, introduced by Representative Gearhart, California, proposes to erect a Veterans' Hospital in California. H R 5371, introduced by Representative Hoepfel, California, proposes to grant hospital treatment and domiciliary care in veterans' hospitals to the retired personnel of the armed services of the United States. H R 5386, introduced by Representative Robison, Kentucky, proposes to provide payment of pensions for disability or death incurred in the regular military or naval service. H R 5549, introduced by Representative Dunn, Pennsylvania, proposes to provide "for workers' health insurance."

CORRECTION

Incubation Period in Tetanus—In Miller and Rogers' article on tetanus in *THE JOURNAL*, January 19, page 188, column 2, it is stated that a short incubation period tends to be a good omen. This is erroneous. A short incubation period offers a bad prognosis, and a long incubation period a good prognosis.

Government Services

OPENING OF THE FEDERAL NARCOTIC FARM, LEXINGTON, KENTUCKY

The first United States Narcotic Farm, near Lexington, Ky., will open for the reception of admissions on or about May 1. It will accommodate a maximum of 1,000 persons and is designed to accommodate males only. Its object and purposes are to rehabilitate, restore to health and train to be self supporting and self reliant those who are admitted thereto. The control management and discipline are to be maintained for the safe keeping of the individual and the protection of the community. Experiments are to be carried on to determine the best methods of treatment and research in this field, and the results disseminated to the medical profession and the general public to the end that states may make some provision for establishing a similar policy for helping to solve the problem of drug addiction. The function of the institution at Lexington therefore assumes the character of a treatment and research center and of an educational and rehabilitation center with certain custodial features superimposed.

Heretofore as far as public policies are concerned drug addiction has been regarded solely as a penal and correctional problem without cognizance being taken of its medical, sociological or economic significance. The institution is to be administered by the United States Public Health Service. As a matter of convenience to Fellows of the American Medical Association, there is herewith printed the regulations governing admissions to that institution.

REGULATIONS GOVERNING THE ADMISSION OF PERSONS TO A UNITED STATES NARCOTIC FARM EFFECTIVE APRIL 1 1935

ARTICLE I—Admissions—1 No person shall be eligible for treatment or confinement in a United States narcotic farm unless he be an addict as hereafter defined and then only (1) if such person has been sentenced to confinement upon conviction of an offense against the United States including convictions by general courts-martial or by consular courts, (2) if such person is completing a sentence of confinement at a narcotic farm and applied in accordance with the requirements of these regulations for further custodial care and treatment beyond the expiration of sentence, (3) if such person is placed on probation by any court of the United States or other Federal authority which has imposed as one of the conditions of such probation that he will submit himself for treatment until discharged as cured or, (4) if such person, being not an unconvicted alien voluntarily signs an application requesting custodial care and treatment in accordance with the requirements of these regulations. Upon admission to a narcotic farm as provided by these regulations such four classes of addicts will be designated and hereafter referred to in these regulations as prisoners, ex-prisoners, probationers' and 'voluntary patients' respectively collectively, they will be designated and hereinafter referred to as 'addicts,' inmates,' patients or beneficiaries.

2 The term addict wherever used in these regulations means any person who habitually uses a habit-forming narcotic drug so as to endanger the public morals health, safety, or welfare, or who is or has been so far addicted to the use of habit-forming narcotic drugs as to have lost the power of self control with reference to his addiction.

3 The terms habit-forming narcotic drug" or "narcotic" wherever used in these regulations mean opium and coca leaves and the innumerable alkaloids derived therefrom, the best known of these alkaloids being morphine, heroin and codeine obtained from opium and cocaine derived from the coca plant, all compounds salts preparations or other derivatives obtained either from the raw material or from the various alkaloids, Indian hemp and its various derivatives compounds and preparations, and peyote in its various forms.

4 A prisoner shall be admitted to a narcotic farm for treatment and confinement therein, upon presentation to the medical officer in charge of such farm of a copy of the sentence and/or commitment, or other certificate showing the conviction, sentence of confinement and commitment of the prisoner, accompanied by an order by the authority vested with the power to designate the place of confinement of the prisoner or of the authorized representative of such authority designating such narcotic farm as the place of confinement and certifying that such convicted person is an addict. Such documents shall be supplemented by the certificate, or a copy thereof, to be ex-

cuted by the prosecuting officer after conviction and sentence on a form prescribed by the Surgeon General, stating his belief that the convicted person is an addict, his reasons for such belief, and all pertinent facts bearing on such addiction, together with the nature of the offense.

5 A prisoner, at the expiration of his sentence at a narcotic farm, may be considered for continued treatment therein as an "ex-prisoner" upon submitting application to the Surgeon General on a form prescribed therefor. Such application must contain an agreement to submit to custodial care and treatment for the maximum time estimated by the Surgeon General as necessary to effect a cure or until he ceases to be an addict and be accompanied by a certificate from the medical officer in charge stating that at least one month prior to the expiration of sentence the prisoner has been examined, that he is still an addict that he may by further treatment in a narcotic farm be cured of his addiction, and estimating the maximum time necessary to accomplish such cure. No prisoner shall be continued for treatment beyond the expiration of his sentence except upon receipt of the Surgeon General's written approval of the application, and then only for such period of time as has been estimated as necessary to accomplish a cure.

6 A probationer shall be admitted to a narcotic farm for treatment upon presentation to the medical officer in charge of an authenticated copy of the order entered by any court of the United States or other Federal authority having power to suspend the imposition or execution of sentence and place a defendant on probation under any existing law, showing that such convicted person has been placed on probation and that the court or other Federal authority has imposed as one of the conditions of such probation that such person shall be admitted and submit himself for treatment at a narcotic farm until discharged therefrom as cured of his addiction, such document shall be supplemented by a certificate executed after conviction by the prosecuting officer or probation officer on a form prescribed by the Surgeon General, such certificate stating the respective officer's belief that the convicted person is an addict, his reasons for such belief and all pertinent facts bearing upon such addiction, together with the nature of the offense.

7 Any addict, except one who is an unconvicted alien, may be considered for admission to a narcotic farm for treatment and confinement therein as a voluntary patient upon filing application with the Surgeon General on a prescribed form. Such applicant must agree to submit to custodial care and treatment for the maximum time estimated by the Surgeon General as necessary to effect a cure or until he ceases to be an addict. Unless he be a beneficiary of the United States Public Health Service as provided by law and regulation, such applicant must agree, if so required by the Secretary of the Treasury, to reimburse the Government for his subsistence, care and treatment and accompany his application by a recognizance, stipulation, bond, or undertaking in form and amount to be approved by the Secretary of the Treasury guaranteeing the cost of his subsistence care and treatment. Such application must be accompanied also by a medical certificate executed on a prescribed form by a qualified physician designated by the Surgeon General. Such certificate must state whether the applicant is an addict, whether the designated physician believes that the applicant may by treatment in a narcotic farm be cured of his addiction, the estimated time necessary to effect a cure, and any further information bearing on the addiction, habits, or character of the applicant that may be pertinent. No such addict may be admitted unless the application is approved by the Surgeon General and unless suitable accommodations are available after all eligible addicts convicted of offenses against the United States have been admitted.

8 The medical officer in charge shall not admit nor accept responsibility for any addict applying or presented for admission to a narcotic farm when in doubt as to the eligibility of such addict or as to the sufficiency of the documentary evidence presented to established eligibility. In such cases he shall report the salient facts together with any recommendation he may desire to make to the Surgeon General for decision. Persons otherwise eligible may be refused admission when accommodations are not available or when appropriations are insufficient for their transportation, maintenance and care.

9 The actual and necessary expenses incident to the transfer to a narcotic farm of prisoners or probationers, including the actual and necessary round trip expenses of custodial officers required in the transfer of prisoners, shall be chargeable to the appropriation for the maintenance of such farm when authorized by the Surgeon General. No payment shall be made from such appropriation for any of the expenses of transporting to a narcotic farm ex-prisoners or voluntary patients.

Socialist Politicians and Misleading Propaganda

The attempt of a woman's organization, "The Maternal Mortality Committee," to represent maternal mortality as connected with malnutrition due to unemployment was reported in *THE JOURNAL*, Dec. 8, 1934 page 1787. The members of the committee passed a resolution stating that they were deeply impressed by the reports of malnutrition among married women in areas of prolonged unemployment and they sent a deputation to the minister of health. He replied that there was no evidence showing a close relation between malnutrition and the maternal mortality rate. Of the deaths examined at least one half occurred among well-to-do people, and it was significant that the maternal death rate for 1933 in such a depressed area as Durham was no higher than in the relatively prosperous county of Middlesex. Nevertheless the conditions in the depressed area were such as to give rise to anxiety and the position was receiving the close attention of the administration. Local authorities had been urged to make full use of their powers, in appropriate cases to supply milk and other foods to expectant and nursing mothers. Attention was being directed to improving the antenatal service insuring the availability of a trained midwife able for all confinements the provision of maternity beds for complicated cases and patients with unsuitable home conditions, facilities for isolation of septic cases, and providing the services of a consultant in difficult cases.

It has been shown by the report of the chief medical officer of the ministry of health that the general health of the population is well maintained in spite of economic difficulties. Indeed he stated that the nutrition of the English people is better today than it has been at any period of which there are records. The infant mortality rate for the quarter ended last September was the lowest ever recorded, being 45 per thousand live births and 7 below the average of the ten preceding third quarters of the year. Yet socialist politicians are constantly representing the people as suffering in health because the government or local authorities do not give more away. The fact is that the unemployed in this country are better off than those in full work in many European countries. But however much the state does in the way of relief, socialist politicians clamor for more and use misleading propaganda.

Transportation of Patients with Fracture of the Spine

In 1931 Mr R. Watson Jones of Liverpool introduced the manipulative reduction of crush fractures of the spine so common in automobile accidents. He pointed out that the kyphotic deformity is one of acute flexion at the site of injury. Therefore reduction can be effected only by the opposite movement. If a patient with crush fracture of the vertebra within a few days of the injury, lies prone with hyperextended spine supported only by his arms at the side of his head and by the front of his thighs and legs leaving the trunk entirely unsupported the body weight alone is sufficient to restore the vertebra that has been crushed into a wedge. Plaster is then applied in this position. This teaching affects first aid treatment. If the patient is put on a stretcher in the usual position on his back this tends to increase the deformity while if he is placed prone the deformity will be reduced. Hence ambulance men have been taught to put the patient in the prone position on the stretcher. However, this practice is not universally accepted, as the following shows.

At the annual meeting of the British Orthopaedic Society, Mr T. P. McMurray of Liverpool said that in fractures of the spine the advantage of face down transportation was that the postural movement necessary for reduction was instituted at once, so that the risk of injury to the cord was minimized. The disadvantages were that patients suffered from shock and that lying on the face embarrassed respiration. There might be fractures of several ribs with danger of visceral injury. He upheld the practice of transporting the patients on their backs. First aid workers could not be expected to diagnose fractures of the spine, and the practice of turning patients over was dangerous. Mr McMurray's recommendation was supported by one surgeon but was opposed by all the others, including Mr Watson Jones who said that ambulance men were already taught to turn these patients over but on their backs, and to lift them by a method that inevitably produced hyperflexion. If a patient with a fracture dislocation was carried in this manner, severance of the cord was inevitable. The association of rib and spinal fractures was so rare as to be negligible and in any event the ribs were more likely to be fractured in front than behind. Professor Haughton of Dublin said that the diagnosis should not give rise to difficulty. If after a severe injury a conscious patient complained of pain in the back and inability to move one or both legs, he should be lifted and carried face downward. Mr H. O. Clarke of Manchester said that there could be no doubt that ordinary face-up lifting was capable of producing paraplegia.

A New Method of Taking Impressions of Finger Prints

Detective Inspector Webber has discovered a new method of taking impressions of finger prints, which has the advantage of dispensing with the camera. The present system is to smear a powder, which brings up the print and this is then photographed. The new powder is merely smeared over the object where a trace of finger print can be detected. Copies are then taken direct on a sensitized paper record. The police authorities are sanguine that the powder will be effective in taking finger prints from dark and dull backgrounds and that a sharp black and white print will be obtainable from even a dull and rough wall. The powder has not yet been officially adopted for general use by the police but there is reason to believe that the final experiments will be successful and that its use will be approved. So far the powder is said to be an unqualified success. Its composition has not been stated.

The War on Locusts in South Africa

South Africa is engaged in the greatest war on locusts in its history. Almost the whole of the union and the neighboring territories are threatened by locusts of one variety or another. Indeed, the only area that is not threatened at present is the coastal belt of the Cape Province. During the last two months an intensive campaign against the hoppers of the brown locust is coming to a successful close. Sixty-two districts, comprising an area of 230,000 square miles, are affected. If South Africa had to fight only the brown locust she would have little to fear but three other varieties are infesting parts of the union. The desert locust has appeared in the Northwest Cape and in the Western Free State and also in Southwest Africa. A campaign will eventually be required against the hoppers of the next generation. The tropical migratory locust is on the increase in the Ceres and Clanwilliam districts of the cape and is causing grave anxiety for the grain producing districts. But it is the red locust that is the greatest danger. Its infestation has been heavy and widespread throughout the year, chiefly in Natal and Zululand and northern Transvaal. Great swarms are converging on the union from the north of which the advanced guard has penetrated deep into the cape district.

Since the locusts first appeared late in 1933, an energetic campaign has been continuously waged against them, which cost \$2,500,000 to the end of June. Success has been only partial and the swarms in the country seriously threaten the closely cultivated sugar districts near the coast. Closeness of cultivation is one of the main obstacles to success. In less settled areas the farmers have been able to protect their crops by mobilizing their employees and other natives, who make a prodigious noise and so prevent the swarm from settling on cultivated ground. When they afterward settle in the open country they are sprayed with a solution of sodium arsenite, of which the government has distributed thousands of tons. But in coastal Natal nearly the whole country is under cultivation and the swarm can only be driven from one field to another.

The employment of sodium arsenite on the swarms that have settled in a cane field is usually effective but causes great damage to the crop. Another method is to singe the insects at night when settled with improvised flame throwers. Some mitigation is hoped for from the larvae of *Stomorphina lunata*, which is said to be breeding rapidly and destroying the locust eggs. The government maintains two airplanes near the Portuguese border, which dust any swarms of locust with sodium arsenite after they have settled. It has proved almost impossible to deal here with swarms from the ground, as the country is exceedingly malarious.

Functional Paralysis Following Injury—Damages Awarded

An unusual case in which a man suffered no physical disability after an automobile accident and yet was awarded damages has occupied a London court. Last August he was struck by a car, which mounted the pavement. He was only slightly bruised and walked home. Fourteen weeks ago he had to go to the hospital and now he could walk a few steps only with difficulty. A physician from the hospital said that he and other physicians were satisfied that the man was not malingering. He was suffering from traumatic neurasthenia. Dr. Henry H. Kessner of Newark, N. J., now lecturing in this country, said that after fifteen years of specialization in industrial act cases in America he was satisfied that the man had no physical disability. It was all a matter of thought. The man had been told that he was in very bad condition and so believed he was. The judge in awarding \$1,750 damages said that if the motorist had struck a man of particularly nervous temperament, that was his ill luck.

The Prognosis in Coronary Occlusion

At the Royal Society of Medicine an important discussion on the prognosis in coronary occlusion was opened by Prof. John Hay of Liverpool. He said that the initial mortality was heavy and quoted the figures of Carey Coombs, who in a total of 144 cases reported forty-nine deaths in or soon after the initial attack. Of the survivors, thirty-two died within twelve months. It could be said that they would all sooner or later die a cardiac death. They could be divided into two groups, the first of which consisted of those in whom cardiac disability was shown by an increasing tendency to dyspnea and a gradual drift toward failure of the congestive type. Pain was not the dominant feature in these patients. This group also included those whose cardiac reserve was further hampered by auricular fibrillation, which might have originated in the attack of occlusion or have begun later and become permanent. The prognosis in this group was bad from the start. Their future was a matter of months. The second group consisted of those who made a satisfactory recovery and could lead reasonably useful lives, though rarely entirely free from some form of cardiac distress. But they learned to live within their limita-

tions and sometimes showed surprising longevity. They eventually succumbed to some kind of cardiac difficulty and seldom from some intercurrent disease. The life of this group could be measured by years. If the first critical stage was weathered, their expectation was from two to five or more years. John Hunter was a classic example. His first attack of coronary thrombosis occurred at the age of 45, twenty years before his death. Three years later he had a second attack, and during the last few years of his life he was liable to attacks of effort angina. Yet he continued to live at high pressure. Professor Hay had one patient who died at 70, fourteen years after his first attack. He was liable to slight angina of effort. In cases of coronary occlusion two facts stood out: (1) the frequency of sudden death, presumably by a terminal thrombosis, (2) the significance of a progressive tendency to dyspnea and congestive heart failure. The younger patients were more apt to recover and their expectation of life was a little longer.

Jan. 3, 1935

Protection of Civilians During Gas Attacks

A sixteen page pamphlet has just been issued by the police department of Paris stating in detail the precautions to be taken by the civilian population during air raids. A large number of illustrations show the character of the shelters that should be sought, which can be rendered as nearly impermeable to penetration by poison gas as it is possible at the present time to imagine. All those who can leave their homes are told to go to the countryside immediately, in order to avoid crowding of the roads leading from the city. If possible, a cellar should be prepared which has very thick walls and into which has been placed water, canned foods and surgical dressings. A cellar 90 feet square can be utilized for only five hours by four persons. All windows in rooms should be tightly closed and a gas mask adjusted immediately if no cellar is available. Civilians are warned not to become panic stricken and are reminded that an active anti-air raid force has been organized. The recent experiences in anti-gas attack maneuvers in England and France have shown that, in spite of ample warning, large cities like Paris and London cannot be fully protected because weather conditions may be such that an enemy plane containing explosive, incendiary or gas shells can escape the vigilance of the defending forces and launch toxic gas or explosives before being stopped. Circulars similar to the Parisian have been published in Russia, Germany and Italy. In Russia, over ten million people, under government supervision, are calling attention to the dangers to civilians and instruction in regard to defense against air raids is compulsory in the public schools. In Germany, this passive defense is well organized and repeated drills are given as to how to behave during gas attacks and every one is advised to be provided with masks. In Italy, all public buildings must contain gas-proof cellars and an effort is being made to build tunnels for civilians. In spite of the Paris police department pamphlet, few citizens have taken the question of gas attacks seriously, having full confidence in the ability of the well organized defensive forces to check any such raids.

Recently the sirens that will give warning of impending raids have been sounded as a trial measure, in all parts of the French capital. To people living as far removed from any potential air-raiding enemy as those in the United States, such elaborate precautions seem unnecessarily alarming, but with the various countries as close to one another as they are in Europe, reminders to civilians that modern warfare is no longer confined to the regions where the opposing armies are in contact do not seem superfluous.

Bladder Function After Spinal Cord Injuries

Since the World War there has been a discussion as to whether voluntary micturition was ever possible after a complete transverse division of the sacrolumbal segments of the spinal cord. Basing their opinion on the experiments of Goltz and Ewald and of Müller, physiologists and neurologists maintain that there is some prospect of voluntary micturition returning. Goltz and Ewald in 1896 observed such a result several weeks after removal of the sacrolumbar and a part of the dorsal portions of the cord in dogs. They believed that nerve centers of sympathetic origin, located in the bladder wall could take over the work of the spinal centers. Müller in 1918 after removal of the sacrolumbar portion of the cord or of the conus terminalis alone in the dog, noted spontaneous expulsion of urine after twenty-five days of retention. This investigator maintained that the centers which controlled the detrusor action were not located in the spinal cord but in the sympathetic ganglions of the pelvis and that these centers continue to function even after division of the cord. This view has been abandoned almost universally and there exists but little doubt that the centers for voluntary micturition are in the spinal cord the transverse division of which always results in retention.

Roussy and Rossi in 1910 found that after removal of the conus terminalis or of the cauda equina in dogs and monkeys the paralysis of the detrusor and abolition of the reflex evacuation of the bladder was permanent (six months) and that there was no reason to assume the existence of extramedullary centers, hence the existence of automatic micturition seemed doubtful.

An important paper on this subject was presented at the Dec 4, 1934 meeting of the Academy of Medicine by Hermann, Morin and Vial. They were able to keep alive for six months a dog whose spinal cord had been removed as high as the level of the first dorsal vertebra. Retention of urine occurred as soon as the cord was destroyed, and the bladder contained at times as much as 900 cc of urine. The bladder emptied itself by the familiar phenomenon of overflow but it was necessary to augment this mode of spontaneous emptying by pressure over the bladder in order to avoid complications. During the first weeks after cord destruction, one could feel the bladder wall contract and expel some urine, but not sufficiently to empty the bladder completely. This occurred also when a thermometer was inserted into the rectum or when the animal's position was changed. One could, of course, think of the possibility of centers of automatic micturition as held by Goltz, Ewald and Müller, but such spontaneous evacuation was only transitory. Hermann and his co-workers explain such a temporary emptying as being due to a hyperexcitability of the detrusor following cord destruction, because it became more and more difficult to empty the bladder by external pressure, until the retention became complete and has remained so. These experiments confirm those of Roussy and Rossi and are opposed to those of the other investigators.

As there is much difference of opinion on the part of neurologists and surgeons concerning the treatment of retention following spinal cord injury, these experiments are of great interest. They show that there is no prospect of a return of spontaneous micturition, even after a long period of observation.

Epileptiform Seizures During Pneumothorax Insufflations

Reflex cardiac and respiratory symptoms following thoracentesis for pleural effusions have been known for some time. Secousse of Bordeaux calls attention to convulsive seizures that have been observed during introduction of air for the purpose of establishing a pneumothorax in tuberculosis. Such reflex irritation of the nervous system occurs especially in cases in which the pleura is very thick as the result of inflammatory

changes. The epileptiform seizures are at first limited to the face or to one extremity and then become generalized. There is also a paralytic form of reflex, preceded by convulsions, but the monoplegia or hemiplegia is of short duration, from a few hours to a few days. One ought to give sedatives before attempting a pneumothorax in nervous individuals, avoid multiple punctures always have a preliminary roentgenogram of the chest and not begin the insufflations until the oscillations of the manometer have ceased and one is certain that the pleural cavity is empty. When epileptiform symptoms appear morphine with caffeine or epinephrine should be given immediately.

Appointments

Prof R. Debre, professor of bacteriology at the Medical School of Paris has just been elected a fellow of the Academy of Medicine, one of the highest honors that can be bestowed on a physician by his colleagues.

Prof T. Bczançon, an authority on pulmonary tuberculosis, has been selected to be professor in that subject, a position which had been occupied by the late Prof. Leon Bernard.

Investigation of Arsenic Poisoning in Wine-Growing Regions

Arsenic poisoning after the drinking of wine was reported in THE JOURNAL, July 23, 1932 page 319. A systematic study of this problem, however, seems to have been conducted only recently, even though chronic arsenic poisoning of this origin has been observed for years in the wine-growing regions of Baden. Because some of the cases were considered occupational diseases the federal ministry of the interior appointed a committee of experts under the directorship of Professor Uhlenhuth to make an investigation. The disorder is surprisingly frequent in the wine-growing region of the Kaiserstuhl. The investigation considered the manner in which the arsenical spraying preparations are employed in the vineyards, the familial hypersensitivity and also other factors among which probably the excessive consumption of the wine with its damaging effect on the liver, plays the most important part. The patients are usually strong drinkers and many of them have cirrhosis of the liver. According to the lecture by Uhlenhuth before the medical society in Freiburg it has to be determined whether the arsenical dusting substances should be entirely prohibited, and whether it would be possible to use other preparations that are free from arsenic (for instance, pyrethrum or nicotine).

Half of the fifty patients were observed by Professor Ziegler in the polyclinic. The arsenic content of the parasitocides amounts to from 4.3 to 7.3 per cent. The most severe symptoms of poisoning occur almost exclusively in dry, volcanic regions. The disorder attacks men almost exclusively. The 'house drink,' which is consumed in large quantities, is obtained by hard pressing of the grape husks. It contains arsenic and is a contributory factor but rarely the only cause. The acute symptoms seem as a rule to disappear within a few days. In some cases, signs of chronic arsenic impairment develop after work is resumed with the parasitocides. These are not simply superficial irritations but a vital universal damaging of the tissues, resulting from the absorption of arsenic. The respiratory tract apparently is the most important resorption surface. During this stage the most noticeable symptoms are those of the skin, characterized by hyperkeratoses on the inner and outer surfaces of the hands, the soles of the feet and the toes. Later there usually appears a small-flecked melanosis of the skin and other well known changes. That the nervous system is involved is indicated by abnormal moods, depression, disturbances in

the memory and polyneuritis, usually of the sensory type, and particularly a hypersensitivity to cold. There are disturbances in the sympathetic and endocrine systems indicated by loss of tonus, disturbances in the vasomotor regulations, impotence, hyperglycemia and true diabetic glycosurias. In case of cirrhosis of the liver, it is possible that both alcohol and arsenic impair the hepatic parenchyma and that these two damaging factors promote each other. The same applies to hemochromatosis. The course of the disease differs in the individual cases. Complete cures have been observed after elimination of the causal factors. Generally the disease takes an unfavorable course and may be drawn out over a number of years. The mortality so far has amounted to 16 per cent. Limitation of working capacity is considerable, even in mild cases. The treatment should begin even in acute cases by administering absorptive substances. In chronic cases the intravenous administration of from 10 to 20 cc. of a 5 per cent solution of sodium thiosulphate is advisable. Later, liver preparations, borax baths and sulphur-salicylic ointment may be applied. The protective measures are of especial importance.

Chemical studies are being made, particularly on the amount of arsenic in the "house drink." As was to be expected, considerable quantities of arsenic were detected in the hair of the patients.

Methods for the Improvement of Spinal Anesthesia

Professor Kirschner, ordinarius for surgery in Heidelberg, has studied methods for the improvement of spinal anesthesia for a number of years. Heretofore, spinal anesthesia has had the disadvantage of the uncertainty of the onset of the anesthesia, particularly in case of operations in the upper portion of the abdomen, also of disturbances caused by a reduction in the blood pressure, in which case the blood vessels of the region became paralyzed, and finally of the indefinite limitation of the effects toward the head with impairment sometimes of the respiratory center.

Kirschner now uses an anesthetic solution, which, owing to the addition of alcohol, is lighter than the cerebrospinal fluid and has a specific gravity of 0.986. Following withdrawal of cerebrospinal fluid, the vertebral canal is partially refilled with the anesthetic solution while the head is lowered. The height of the anesthesia may be determined by quickly testing the sensitivity. The upper limit may be determined exactly, it should never go higher than the mamilla. When the anesthesia subsides, feeling returns first in the legs. The blood pressure is as a rule not at all reduced. The quantity of the anesthetic is small, for instance, 2 cc. of a 0.5 per cent solution of nupercaine. In extremely excitable patients, from 0.2 to 0.3 mg. of scopolamine is administered intravenously. The postoperative pain usually is still dulled on the following day. Eventually the after-pain takes the form of a headache, but this is usually not severe and the remedy is the intravenous injection of a 20 per cent solution of dextrose. This anesthesia has thus far been tried in 2,000 cases. It has only a slight influence on the organism as a whole. Icterus and diabetes are not contraindications. It is unnecessary to hurry the course of the operation. Disadvantages of the method are that the operation requires from twenty to thirty minutes of preparation and that the operation must be performed in the Trendelenburg position.

Advertising Remedies at Public Lectures

Several months ago the ministry of the interior directed that it should be determined in each case whether there is reason for the prevention of a lecture in which are discussed certain curative methods or procedures, "without confusing the population and without advertising definite remedies." The regulation that lectures of this type should not be prohibited seems to have been abused. While definite remedies are not advertised

in the lecture itself, following the lecture the persons who attended and whose addresses were taken on entering the lecture hall are solicited by agents of the firm that makes the remedies or apparatus. Such a procedure evades the regulations and cannot be tolerated. The minister admits that there may be some need for reliable apparatus for the preparation of water that contains radium emanations for drinking or bathing, as well as radium cushions or compresses, but it cannot be admitted that such products should receive especial recommendation in public lectures. Moreover, the representatives of firms who produce such radioactive apparatus are not suited to enlighten the people in matters of health. In this connection it may be mentioned that recently the "biochemical society" (this misleading name has nothing in common with biochemistry as a physiologic science) of Berlin put posters on numerous houses informing the public that it would give "information and consultation in all types of illness." The federal minister of the interior considered such advertisement for a "natural method of healing" as undesirable and prohibited the performance.

The Germans Spend Millions for Alcoholic Beverages

The expenditures for alcohol in Germany during the year 1933-1934 amounted to 3,042 million RM. The acreage of viticulture, which had gradually decreased since 1911, has again increased in the last two years. The wine consumption amounts to about 4 liters per capita, the average cost of which may be estimated as 4.40 RM. The efforts to create a greater market for the German wines have been unsuccessful as a result of the simultaneous advance in prices. An essential detriment for greater wine consumption is the preference for beer, for which the competition was eased by special tax reductions. That the population expended 546 million RM for distilled liquors during the year 1933-1934 (April 1 to March 31) is to be considered with grave concern. Per capita, the inhabitants of Germany consume 0.814 liter of alcohol, or 2.32 liters of drinkable liquor with 35 per cent of alcohol by volume. This represents an expenditure of 8.57 RM per capita. The expenditure for beer during the same period with a total consumption of approximately 34 million hectoliters, amounted to 2,206 million RM, that is, a per capita expenditure of 33.8 RM for 51.8 liters each.

MEXICO

Dec. 29, 1934

The Want of Special Regulations Concerning the Practice of Medicine

The present constitution of Mexico was promulgated in 1917. There is a statement in article 4 that the practice of certain professions will be governed by special regulations concerned with the designation of the schools and authorities which are empowered to give diplomas and licenses to practice. Seventeen years has passed and the special regulations are not, as yet, in effect. Because of the propaganda made by the homeopaths, especially through the newspapers, some physicians have recently published articles which are aimed at stopping the practice of homeopathy. A controversy has developed and the homeopaths are now challenging the physicians, through the press, to debate before the public (1) whether or not homeopathy is based on scientific grounds, (2) whether it is a rational method for the cure of disease, (3) whether it is a method recognized also in some other countries and (4) whether medicine has in any form derived any benefit from homeopathy.

Improvements at the General Hospital

The General Hospital of Mexico City, because of improvements recently made, will be in the near future an important medical center. A maternity department adjoining the hospital has been opened with the help of a bequest in the will of

Señora Lavin and an appropriation from the board of public welfare of the city. The building is modern, with large halls and comfortable rooms for pregnant women and for infants, and has well equipped rooms for operations and treatment. There are 300 beds.

Another great improvement is the children's hospital, a six story building adjoining the General Hospital, the construction of which will be finished soon. The building has room for 600 children, with excellent arrangements for sunlight and air.

The General Hospital is made up of pavilions, each of which has forty beds and is encircled by gardens. This disposition has disadvantages in connection with the transport of patients after operations. To avoid the inconveniences, the separated pavilions are to be united in only two large wings for surgery and for internal medicine respectively, each of which will contain 500 beds. Two additional pavilions are to be constructed for infectious diseases and for specialties. The General Hospital as a whole will have, through the various improvements, a total of 3,000 beds.

A Physician Appointed President of the University of Mexico

The pay of teachers of the University of Mexico and other expenses in the university were reduced during 1934 on account of economic conditions. The federal government has given the university through the secretariat of public education 5,000,000 Mexican pesos (about \$1,350,000) for expenses in 1935. At the same time Dr. Fernando Ocaranza, who for many years has been a professor of the School of Medicine and later director of the school, has been appointed head of the university. The medical school, during its centennial celebration in 1933, received several gifts, which made possible new laboratories of chemistry and bacteriology, and an amphitheater for dissecting and experimental work. A new department for clinical research will begin to function in 1935.

Campaign Against Leprosy

According to the latest census, there are about 2,000 lepers in the country. The campaign against leprosy has recently been intensified by the department of public health. A new dispensary for lepers was recently opened in Mexico City and five more are going to be opened in various states. All the dispensaries will be functioning in March and will have a personnel of specialized physicians, nurses and other workers. Three leprosariums at a total cost of 300,000 Mexican pesos (about \$81,000) will be constructed.

Onchocerciasis

A careful study of the transmission of onchocerciasis is being carried on by a special committee under the chairmanship of Dr. Salvador Gonzalez Herrejon. The condition has been found in persons living in the mountains of Oaxaca. The causal agent is a simuliid which transmits the infestation by its bite. The infestation results in blindness and mental disturbances. In some regions 80 per cent of the population is blind. The treatment of the condition is surgical and not very promising. A comprehensive monograph on the habits and reproduction of the simuliid is in preparation and will serve as a basis for the campaign against onchocerciasis. Dr. Gonzalez Herrejon has already published articles on his early observations. His work has been considered of great importance both in Mexico and abroad.

Meeting of Biologic Society

The Sociedad Mexicana de Biología held its annual meeting in Mexico City, October 22-26. The following articles were presented and discussed: the serologic relation between endemic and epidemic typhus in Mexico City, by Dr. Hermann Mooser, the bicolorimetric method for determination of *pu*, Dr. Juan Roca, thalamencephalohypophyseal histologic entity, Dr. Ana-

stasio Vergara C., Mexican mosquitoes, Dr. Alfonso Dampf, blood groups in childhood from a biologic point of view, Dr. Jose F. Franco, meningitis encephalitis of bovine, Dr. Javier Escalona, *Bacillus Welchii* isolated from the intestine, Dr. Pedro Vera, experiments with typhus antiserum, Drs. Gerardo Varela and Miguel Angel Parada.

Vaccination Departments

Vaccination departments for school children will be in operation during January of this year in about seventy different dispensaries of public health and welfare of the city and in different hospitals. Adults also will be vaccinated, if they wish, at the same stations. The vaccination of Indians in the rural districts is carried on without any difficulty now, as they have learned of its value and the lack of danger attending vaccination.

Visceral Leishmaniasis in Brazil

Dr. H. Penna recently reported the presence of visceral leishmaniasis in Brazil. With the aim of discovering evidence of any yellow fever that might be present, a branch laboratory was established in 1930 in northern Brazil. A histologic study of the liver of persons who died within ten days from the onset of their illness was made. The study yielded data on (1) the presence of yellow fever in towns and villages apparently free of the disease, (2) the distribution of some other diseases, such as malaria and schistosomiasis, and (3) the presence of hepatic lesions indicating visceral leishmaniasis (kala-azar), a disease not previously reported in Brazil. The material examined consisted of sections of liver taken from cadavers with a viscero-tome, which were then fixed in a 10 per cent solution of formaldehyde and stained by hematoxylin-eosin. The sections showing leishmaniasis are characterized by the presence of organisms having the appearance of *Leishmania*, enclosed in large cells of the macrophage type inside the liver capillaries. The parasitic cells are round, about 2 microns in diameter, and have a nucleus and a kinetoplast both of which take hematoxylin, although they are more distinct when the Romanowsky stain is used. With the Giemsa stain the cytoplasm stains light blue and the nucleus darker blue, while the kinetoplast strongly stains a yellow red. The nucleus is round and the kinetoplast is rod shaped. In a study by comparison of liver sections, prepared by Penna and of sections from authentic cases of kala-azar prepared by Dr. H. B. Aragão, no difference could be observed. The organisms obtained by Penna when compared with those of experimental leishmaniasis caused by *Trypanosoma Cruzi*, as seen in the liver, spleen and adrenals of inoculated dogs, showed some differences, especially related to their size. The organism isolated by Penna probably belongs to the form of *Leishmania* reported by Ross in 1903. Cultures have not been prepared as yet, because no clinical cases have been observed. Leishmaniasis lesions were found in forty-one sections from a total of 47,000 liver sections examined up to Sept. 30, 1934. The earliest age in the whole group was 45 days and the most mature, 56 years. Probably the figures of 1 per thousand of visceral leishmaniasis do not represent the actual proportion of the disease in Brazil, since it was found only in a selected group of persons who died within ten days of the onset of a disease. The study, as said before, was intended to discover the presence of yellow fever, which has a more rapid course than that of visceral leishmaniasis.

Carlos Chagas

Dr. Carlos Chagas, head of the Instituto Oswaldo Cruz and the discoverer of American trypanosomiasis (Chagas' disease), is dead. Dr. Chagas was born in Oliveira, Minas Geraes, in

1879 and he graduated from the School of Medicine of the University of Rio de Janeiro in 1903. He was appointed chief physician to the public health hospitals in 1904, head of the committee for prevention of malaria in Minas Geraes in 1905, assistant head of the Instituto Oswaldo Cruz in 1908 and head of the institute in 1917. He was appointed head of the commission for the study of malaria in the Amazon River region in 1912, head of the campaign against influenza in 1918, was director of public health in Rio de Janeiro from 1919 to 1926, professor of tropical medicine in the Faculty of Medicine of Rio de Janeiro in 1925, a permanent member of the Committee of Hygiene of the League of Nations in 1925 and technical head of the International Institute of Leprosy in 1933. He was awarded the Schaudinn prize and in 1925 the Kummel prize given by Hamburg University. Degrees and offices that he held included doctor *honoris causa* by the universities of Paris in 1926, of Lima in 1929 and of Howard and Brussels in 1933, honorary professor of the Universities of São Paulo and Minas Geraes and of the School of Medicine of Bahia, honorary member of the national University of Buenos Aires and of the University of Arequipa, doctor in agrarian sciences by the University of Buenos Aires, member of the Academy of Medicine of Paris of the Society of Tropical Medicine and Hygiene of London and of medical societies in Lima, Germany, Italy, New York, Belgium, Chicago and other places. Dr. Chagas was president of the Pan-American Conference of Pathology, Microbiology and Hygiene in Rio de Janeiro in 1929 and a delegate to the seventh Pan-American Conference in Montevideo in 1933 to the International Conference of Parasitology and Microbiology in Buenos Aires in 1916 to the Congress of Malaria in Rome in 1923 and to the International Congress of Hospitals in Atlantic City in 1929. He was invited to lecture in many places abroad and was honored with the following medals: Legion of Honor from France, the Order of Italy, the Order of Belgium, the Order of Alfonso XIII, the Order of Isabel la Católica and the Order of Rumania.

Can Alcohol in the Human Body Become Ignited?

It is a popular belief in Rumania that the body of a person, soaked with alcohol, is combustible. Prof. A. Elfer of Cluj, in a popular lecture before the Hygienic Society, said that in past centuries it was earnestly deemed possible that the alcohol laden breath of a tippler may catch fire from the glow of an oven or even from his own pipe. Cases of "combustio spontanea," the burning of the body of itself, have been reported especially in France, the first one in 1725. From the study of several hundreds of recorded cases it is evident that "self igniting" (this was its scientific term at that time) was more frequent with women than with men, more common in winter than in summer, and more common in cases of acute drunkenness than in the normal condition, and it is probable that they were simply accidents to which drunken persons being careless, become victims by setting their clothes on fire. However, from the point of view of forensic medicine it is important to decide whether such self ignition of the body is possible. It was alleged in 1847 that the countess Gortitz became ignited spontaneously in Darmstadt, Germany and burned to death. A commission whose members included the greatest chemical experts of the age, Liebig and Bischoff, studied this case and completely refuted the theory of spontaneous combustion. The commission found that the human body, soaked with ever so much alcohol could not ignite of itself by any means, nor could it easily be set on fire. In the decomposition of a corpse inflammable gases may develop but not even the ignition

of these will lead to incineration. Liebig's investigations refuted the theory of self combustion for once and for all, but in eastern Europe the topic is still of great interest to laymen.

The Blind in Rumania

Dr. Virgil Popovici, senior physician to the Institute for Blind People in Temisoara, has written a little book on the blind in Rumania. According to this book, 34.5 per cent of all blind people of Rumania live in the Banate, 21.6 per cent in Transylvania, 6.64 per cent in the old kingdom, and 2.7 per cent in Bucovina. Banate is the province most infested by trachoma. Although the Hungarian government and its successor, the Rumanian government have established dispensaries even in the remotest villages where free treatment and instruction as to protection against this scourge is obtained trachoma is still difficult to eradicate. Popovici says that in Rumania there are only 64 blind persons per hundred thousand of population. As to the nationality of the blind people, 46 per cent are Rumanians, 24 per cent Germans, 30 per cent Magyars, 6 per cent Jews, and 4 per cent Slavs, 41 per cent of the blindness is congenital. Dr. Popovici urges the formation of an association to aid the blind industrially and culturally and to conduct a campaign to defeat the conditions and causes that lead to blindness.

Tuberculosis in Rumania

Dr. Mangiurea, director of the demographic bureau, reports that the number of tuberculosis patients in Rumania is about 400,000 and that the hospital and sanatorium beds at the disposal of these patients is 2,004 less than it was in 1926. It is imperative to provide at least 18,000 beds for these patients. Under the present critical economic conditions there is little hope that this can be accomplished. In the last three years only one new sanatorium has been erected by the ministry of public health, the one in the forest of Pantelimon near Bucharest. Two small sanatoriums in Filaret and Zerlend, were closed, as they did not meet the requirements of the times.

The mortality from tuberculosis is about 27 per thousand of population. In the villages and 15,200 tuberculous patients succumb annually, without having had medical care. Rumania spends one leu (at present about 1 cent) on tuberculosis per capita of the whole population, other countries spend from 20 to 100 lei.

Marriages

THOMAS LAURIN GRITZKA, Talmage, Neb. to Miss Lila Maude Lehman of Formosa, Kan., Nov. 18, 1934.

TERRY BIRD, Panama City, Fla. to Miss Eleanor Conner of Tallahassee at Headland, Ala., Dec. 30, 1934.

IRA MILBURN DIXON, Stockbridge, Mass. to Mrs. Elizabeth Barber Hoffmann of New York, January 24.

ROBERT HENRY DE JARNETTE, Dahlonga, Ga., to Miss Mary Lou Gates at Mount Vernon, Dec. 27, 1934.

JULIAN BUSBY, Kannapolis, N. C. to Miss Margaret Little of Greensboro at Lexington, Dec. 24, 1934.

ROBERT STUART ROBERSON, Hazelwood, N. C., to Miss Eunice Simons of Colerain, Dec. 27, 1934.

THEODORE MORRISON CRAIN, Monterey, Tenn., to Miss Effie Judd at Harriman, Dec. 21, 1934.

VIOLETTA G. SHELTON, Los Angeles, to Mr. Etienne Girardot at Yuma, Ariz., Dec. 30, 1934.

ORCENA F. KNEPPER to Mr. J. Irvine Lyle III both of Plainfield, N. J., Sept. 10, 1934.

JOSEPH MEREDITH BOOMER, Omaha, to Miss Naomi Schleiger of Lincoln, Neb., recently.

LEO DAVID O'KANE, Fullerton, Neb., to Miss Adelle Sindelar of Howells, Dec. 3, 1934.

Deaths

Ernest Oliver Joseph Eyttinge ♂ Lieut, Commander, U S Navy, retired, Redlands, Calif, Columbia University College of Physicians and Surgeons, New York, 1904, entered the navy in 1905 and retired in 1919 for incapacity resulting from an incident of service, fellow of the American College of Surgeons, formerly secretary of the San Bernardino County Medical Society, attending neurologist to the San Bernardino County Hospital, aged 54, died, January 20 of injuries received when the automobile in which he was driving overturned

William Henry Bucher ♂ Lieut, Commander, U S Navy, retired, Olive View, Calif, Medico-Chirurgical College of Philadelphia, 1896, entered the navy in 1898 and retired in 1909 for incapacity resulting from an incident of service, veteran of the Spanish-American and World wars, medical superintendent of the Olive View Sanatorium, aged 60 died, Dec. 30, 1934, at his home in San Fernando, of pneumonia

Charles Carroll Habliston, Baltimore, University of Maryland School of Medicine, Baltimore, 1914, member of the Medical and Chirurgical Faculty of Maryland and the American Clinical and Climatological Association, associate professor of medicine at his alma mater, served during the World War, on the staff of the Baltimore City Hospitals, aged 44, died, January 17, of heart disease

Henry Webster Bortner, Everett, Wash, Ohio State University College of Medicine, 1914, member of the Washington State Medical Association, past president of the Snohomish County Medical Society, aged 45, served during the World War, member of the staffs of the General Hospital and the Providence Hospital where he died, January 8, of cirrhosis of the liver and nephritis

John Alexander Campbell ♂ Williamsport, Pa, College of Physicians and Surgeons, Baltimore, 1901 member of the House of Delegates of the American Medical Association, 1924-1927, 1929-1931, treasurer and past president of the Lycoming County Medical Society, on the staff of the Williamsport Hospital, aged 59, died, January 4, of influenza and pneumonia

Percy Betterman Battey, Bedford, Hills N Y, John A Creighton Medical College, Omaha, 1911, member of the Connecticut State Medical Society, the American Psychiatric Association and the American Orthopsychiatric Association, served during the World War, medical superintendent of the Westfield State Farm, aged 46, died, January 3, of heart disease

George W Bushong, Tompkinsville, Ky, Hospital College of Medicine, Louisville, 1897, member of the Kentucky State Medical Association, county health officer for many years postmaster, also a druggist, on the staff of the Samson Community Hospital, Glasgow, aged 62, died, January 7, in St Thomas Hospital, Nashville, Tenn, of pneumonia

George Edgar Dean, Scranton, Pa, University of Pennsylvania School of Medicine, Philadelphia, 1877, member of the Medical Society of the State of Pennsylvania, formerly county coroner, aged 81, for twenty-one years on the staff of the Lackawanna Hospital, now known as the State Hospital, where he died, January 12, of bronchopneumonia

Robert James Carlisle ♂ New York, Bellevue Hospital Medical College, New York, 1884, professor of medicine, University and Bellevue Hospital Medical College, aged 75 consulting physician to St Joseph's Hospital, Far Rockaway, the Bronx Hospital and Bellevue Hospital, where he died, January 15, of coronary thrombosis

Zadock Troxell Kalbaugh ♂ Piedmont, W Va, University of the City of New York Medical Department, 1891, fellow of the American College of Surgeons, veteran of the Spanish-American and World wars, bank president, for many years member of the city council, aged 65, died, January 11, of cerebral hemorrhage.

Thomas Donald Keckich ♂ Gary Ind, Rush Medical College, Chicago 1926, associate in ophthalmology, Northwestern University Medical School, Chicago, served during the World War, aged 36, on the staffs of the Methodist Episcopal Hospital and St Mary's Mercy Hospital, where he died, January 9, of pneumonia

Howard Clarke ♂ Honolulu Hawan Tulane University of Louisiana Medical Department, New Orleans, 1905, fellow of the American College of Surgeons served during the World War on the staffs of the Queen's, Children's and St Francis hospitals, aged 51, died, January 6, of carcinoma of the stomach.

George Frederick William Buttschardt, Queens Village, N Y, University and Bellevue Hospital Medical College, New York, 1902, member of the Medical Society of the State of New York, formerly on the staff of the Bethany Deaconess Hospital, Brooklyn, aged 61, died, January 21, of angina pectoris

Chester Caldwell Funk, New Albany, Ind, University of Louisville (Ky) Medical Department, 1903, member of the Indiana State Medical Association, formerly health officer of New Albany, served during the World War, on the staff of St Edward's Hospital, aged 54, died, January 15, of angina pectoris

James Melvin Delevett, Baltimore, Baltimore Medical College, 1903, member of the Medical and Chirurgical Faculty of Maryland, formerly member of the school board, aged 62 formerly chief resident physician of the Maryland General Hospital, where he died, January 18, of pneumonia

Isaac Lycurgus Van Zandt, Fort Worth, Texas University of Louisiana Medical Department New Orleans, 1866, member of the State Medical Association of Texas, Civil War veteran, aged 95, died, January 10, of heart disease, prostatic obstruction and nephritis

Frona Abbott, Denver, Denver Homeopathic College, 1899, formerly professor of hematology at her alma mater, aged 65 died, Dec 28, 1934, in the Los Angeles General Hospital, of injuries received when the automobile in which she was driving was struck by a truck

Minta Proctor Kemp, Philadelphia, University of Michigan Medical School, Ann Arbor, 1900, member of the Medical Society of the State of Pennsylvania, aged 59, on the staff of the Friends Hospital, where he died, Dec. 29, 1934, of carcinoma of the liver

Anthony Cristiana Bavuso, Framingham, Mass, Middlesex College of Medicine and Surgery, Cambridge, 1927, member of the Massachusetts Medical Society, aged 32, on the staff of the Framingham-Union Hospital, where he died, Dec. 30, 1934, of pneumonia

Victor James Capron ♂ Friday Harbor, Wash Jefferson Medical College of Philadelphia, 1888, formerly member of the state board of health, state legislature, and mayor of Friday Harbor, aged 67, died, Nov 16, 1934, in the Virginia Mason Hospital, Seattle

Richard Theodore Bang ♂ New York, College of Physicians and Surgeons, Medical Department of Columbia College New York, 1879 formerly attending physician, outpatient department, New York Hospital, aged 79, died, January 16, of heart disease.

David Lauderdale Bryson, Calhoun Falls, S C Atlanta College of Physicians and Surgeons, 1910, member of the South Carolina Medical Association, aged 52, died, January 5, in the Anderson (S C) County Hospital, of cardiovascular renal disease

Frank Cline Shipman, Jersey City, N J, New York Homeopathic Medical College and Flower Hospital, 1908 member of the Medical Society of New Jersey, aged 54, died, January 5, of hemorrhage resulting from carcinoma of the tongue.

William Wallace Kinkead, Nashville Tenn, Columbus (Ohio) Medical College, 1882, University of Tennessee Medical Department, Nashville, 1886, veteran of the Spanish-American War, aged 77, died, January 6, of carcinoma of the cecum

Charles Henry Chesebro, Utica, N Y, University of the City of New York Medical Department, 1884, member of the Medical Society of the State of New York, aged 76, died, Dec. 14, 1934, of cerebral softening and arteriosclerosis

Oreste Castagna, New York, Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1901, member of the Medical Society of the State of New York, aged 57, died, January 14, of a self-inflicted knife wound of the heart

Walter Scott Bell ♂ Elsie, Mich State University of Iowa College of Medicine, Iowa City, 1897, on the associate staff of the Clinton Memorial Hospital, St Johns, aged 62, died, January 19, of carcinoma of the urinary bladder

Daniel Francis Hochdoerfer, St Louis, Beaumont Hospital Medical College, St Louis, 1889, for many years coroner's physician, formerly of the staff of the Alexian Brothers' Hospital, aged 66, died, January 8, of carcinoma

Joseph Parsons Comegys ♂ New York, College of Physicians and Surgeons, Keokuk, Iowa, 1890, Jefferson Medical College of Philadelphia, 1891, served during the World War aged 69, died January 20, of pneumonia

Henry V Byers, Newton, Iowa, Eclectic Medical Institute, Cincinnati, 1875 member of the Iowa State Medical Society, aged 86 died, January 5, in the Mary Frances Skiff Memorial Hospital, of heart disease

Dexter Peter Cannaday, Roanoke, Va., Medical College of Virginia, Richmond, 1905 member of the Medical Society of Virginia, aged 57, died, Nov 11, 1934, of pneumonia, following perforated duodenal ulcer

Warren Henry Hoey, Newton, Mass., Harvard University Medical School, Boston, 1902 member of the Massachusetts Medical Society served during the World War, aged 53, died, Dec. 31, 1934

Cicero Holcomb Cox, Waynesboro, Ga., University of Georgia Medical Department, Augusta, 1886 past president of the Burke County Medical Society, aged 68, died January 17, of pneumonia

Joseph Hector Bainton ♂ New York, Columbia University College of Physicians and Surgeons New York 1901 on the staff of the Morrisania City Hospital, aged 59, died, January 7, of coronary occlusion

Charles Thomas De Loach, Sarepta, La., Memphis (Tenn) Hospital Medical College, 1905 member of the Louisiana State Medical Society aged 54, died Dec 25, 1934, of cerebral hemorrhage

Addison Milton Rathbun, Rice, Minn. Rush Medical College, Chicago 1878 member of the Minnesota State Medical Association aged 80, died, Dec 13 1934, of myocarditis and diabetes mellitus

Francis Elgin Prewitt, Phoenix, Ariz. Gross Medical College Denver, 1898 formerly police surgeon in Denver aged 66 died, Nov 25, 1934, of cerebral hemorrhage and myocarditis

Edward Harris ♂ Cumberland Md. Hahnemann Medical College and Hospital of Philadelphia 1902 aged 55, on the staff of the Memorial Hospital, where he died, January 22, of pneumonia

William Woolsey Bellamy, Watertown Mass. Harvard University Medical School, Boston 1902 member of the Massachusetts Medical Society, aged 57, died, January 17, of pneumonia

Frederic Burton Cornell, Aurora Colo. College of Physicians and Surgeons, Baltimore 1902 aged 58 died, January 16 in the Colorado General Hospital, Denver, of heart disease

Foster Wand Burke ♂ Laclede, Mo., Marion-Sims College of Medicine, St. Louis, 1897, formerly secretary of the Linn County Medical Society, aged 60 died, January 3, of heart disease.

Robert Joseph Kirkwood Jr., Boston Harvard University Medical School, Boston, 1925 served during the World War, aged 38, died January 3, of angina pectoris and coronary occlusion

James Wesley Ellis, Owensboro, Ky., Jefferson Medical College of Philadelphia, 1870 past president of the Kentucky State Medical Association, aged 88, died, January 4, of senility

Lincoln Mock Bowman, Alton, Ill., Rush Medical College, Chicago, 1886, member of the Illinois State Medical Society, aged 74, died, January 9, of heart disease following pneumonia

Watson H. Harwood, Chasm Falls, N. Y., University of Vermont College of Medicine Burlington, 1881, aged 80 died, Dec 22, 1934, of heart disease and hypertrophy of the prostate

Wilson David Forsythe, New Concord, Ohio, Starling Medical College, Columbus, 1891, member of the Ohio State Medical Association, aged 75, died, January 12, of toxemia

George W. Fleming, Petittodiac N. B., Canada, McGill University Faculty of Medicine Montreal, Que., 1893, aged 72, died Nov 7, 1934, in Montreal following a prostatectomy

William O. Mabry, Goodman, Miss., Memphis (Tenn.) Hospital Medical College, 1897, member of the Mississippi State Medical Association aged 61 died, Dec. 27, 1934

Chauncey Elder Kirk, Pittsburgh Western Pennsylvania Medical College Pittsburgh 1894 aged 63, died, Dec 29 1934, in St. Joseph's Hospital of chronic nephritis and uremia

Valentine Hummel Fager ♂ Harrisburg Pa. University of Pennsylvania School of Medicine, Philadelphia, 1892, aged 68 died, Dec 22, 1934, of coronary thrombosis

William Andrew Fulton, Burlington, Wis. Rush Medical College, Chicago 1893 member of the State Medical Society of Wisconsin, aged 66 died, January 26, of influenza

William Homer Conklin, Ansonia, Conn., University of the City of New York Medical Department, 1882 aged 74 died, January 11, of chronic myocarditis and nephritis

Orrie Ianthas Hetsler ♂ Blountsville, Ind., Eclectic Medical Institute, Cincinnati, 1896, aged 63, died, January 19, in the Ball Memorial Hospital, Muncie, of pneumonia

James Leslie Cannon, Toledo, Ohio, Medical College of Ohio, Cincinnati, 1901, served during the World War, aged 62 died, January 14, of carcinoma of the prostate

DANGERS OF TETANUS ON PUBLIC BEACHES

To the Editor—In the instructive and interesting survey by Drs Miller and Rogers of the present status of tetanus (*THE JOURNAL*, January 19, p 186) I note the following passage "Ordinary wounds acquired in the home or in *clean places* [*italics mine*], free from possible fecal contamination, or *while bathing at the shore* [*italics mine*] should not require the injection [of antitetanus serum]." Many medical practitioners have the experience, or at least the impression that "shore" injuries are often complicated by tetanus. Few 'metropolitan' beaches if any, are free from possible fecal contamination. Wreckage containing rusty nails, wire and corroded metal odds and ends of garbage and other jetsam and flotsam, broken clam shells and bottles, sharp stones, wood splinters, and so on, are present in abundance. Of thirty-three cases listed in abstract by the authors of the paper, nine at least gave a history of injuries such as might well have been received while in bathing or playing on the beach. Perhaps it might be the part of prudence to add "beach injuries" to the compound fractures, gunshot wounds, deep punctured wounds, street wounds' and "farm wounds" that should all be treated prophylactically.

PERCY FRIDENBERG, M.D., New York.

INTRACAPSULAR FRACTURE OF THE HIP

To the Editor—I note in the paper by Drs Howard and Christophe on the treatment of intracapsular fracture of the hip at the Massachusetts Memorial Hospitals (*THE JOURNAL*, Dec. 15, 1934, p 1833) that the purpose is to compare the end results of treatment by the "abduction double spica of Whitman with those of the traction methods of Ruth and Peckham." This suggests the following comments:

1 That there is no "Whitman double spica" since I have never used such an appliance.

2 That the abduction treatment is quite independent of the external appliance. It is in essence the utilization of anatomic mechanics to correct deformity and to oppose and fix the fragments. The function of $\frac{3}{8}$ external splint is simply to support the limb in the attitude that assures the anatomic fixation, namely, complete abduction, complete extension and slight inward rotation. For this purpose plaster of paris is the only means generally available, and the long spica, which leaves the other limb free is in my opinion the most comfortable and the most effective splint.

It may be noted furthermore that the abduction method is comprehensive in its scope, including the incomplete fractures of childhood, the epiphyseal separations and fractures at the base of the neck, as well as those with which the paper under consideration is directly concerned.

Finally, it has extended the range of effective treatment to extreme old age.

In this connection it may be noted that the death rate at the Massachusetts Memorial Hospitals (21.1 per cent) is far above the average of other statistics. Stern and his associates, for example, have reported seventy-seven cases of medial fracture treated by the abduction method in a Cleveland hospital. Twenty-eight of the patients were between 60 and 70 and seventeen were between 70 and 80 yet the mortality was but 7 per cent (*Surg Gynec & Obst* 53:250 [Aug] 1931).

Formerly treatment of patients of this class was purely symptomatic, yet the mortality was high and I think it may be assumed that the death rate that can be attributed directly to treatment must be low.

I conclude that the relative advantages of the abduction treatment in the comprehensive range gets effectiveness and its practicability under all conditions are so obvious that one who has been trained in its application and in the further details of the treatment will find little occasion for substitutes.

ROYAL WHITMAN, Sunningdale, Berks, England

HIGH FAT DIETS IN GALLBLADDER DISEASE

To the Editor—Are high fat diets beneficial to patients with gall bladder disease or stone? My question is prompted by the well known olive oil cure for gallstones. What is the opinion of competent authorities on this subject? Is it not a fact that high blood cholesterol will tend to increase the formation of stones because high fat feeding, especially with eggs, increases cholesterol? Please omit name.

M.D. Ohio

ANSWER.—It is a common practice to forbid fats to patients with gallbladder disease. The ideas back of the practice are several. First, it is thought that with the lowering of cholesterol in the blood there will be less tendency to the formation of stones, second, that with the mechanism for the concentration and storage of bile out of order, the digestion of fats may suffer, and third that, actually, patients with gallbladder disease often do better if they avoid the eating of fat and particularly of large meals rich in fat.

It seems foolish to worry about the cholesterol content of the blood in patients with gallstones, because every pathologist and surgeon knows that in most cases it looks as if the stones had been formed at one time because they are all alike in color and composition. Only occasionally does it appear that there must have been two or three separate episodes in which stones of different types were formed. It seems then that the woman who gets two big gallstones perhaps during her first pregnancy at the age of, say, 22 years, will have these two stones and no more when she is operated on, say, at the age of 50 years. Under these circumstances it seems foolish to impose dietary restrictions with the hope of saving the woman with cholelithiasis from getting more stones. Besides, there is little reason for assuming that the acquisition of a few more stones would influence the clinical picture. So far as is known, it is the coming of infection that changes a "silent" gallbladder full of stones into a painful and menacing gallbladder.

The "well known olive oil cure" is really no cure at all, it is usually the device of a quack to collect money for the extrusion from the bowel of a lot of pellets of castile soap (made in the intestine from the olive oil), which are thought by the victim to be gallstones.

There is considerable evidence to indicate that women in many parts of the Orient seldom suffer with gallstones, and this has been thought to be due to a consumption of fat lower than that common in Europe or America. Actually, in the absence of exact information or of knowledge in regard to other possibly more important factors, these observations of missionary physicians and others cannot be stressed. It may be that the missionary doctor sees few gallstones because he rarely gets a chance to operate on or to perform necropsies on old women. They are too conservative and too fearful of the "foreign devil."

So far as we know, no one has been able to produce gallstones in man by feeding diets high in cholesterol. Some experiments on animals have shown that during the normal concentration of the bile in the gallbladder conditions might arise in which there would come an abnormal proportion between the concentrations of cholesterol and of bile acids. Under these conditions, stone-forming material might be precipitated. Others believe that infection is the most important factor, while others ascribe everything to stasis.

In the present state of experimental and clinical knowledge, the only conclusion seems to be that there is no logical diet for cholecystitis or cholelithiasis, and in actual practice no physician with an open mind and a large experience in this field would ever hope to put a stop to flare ups of cholecystitis by prescribing a diet. This may sound like black heresy to physicians in Europe who make their living at watering places by treating patients with cholecystitis, but any gastro-enterologist of experience knows that, commonly, these patients, after perhaps a temporary improvement due to rest, more careful eating and purgation, get into trouble again.

EXAMINING URINE FOR SUGAR

To the Editor—Five cubic centimeters of qualitative Benedict's solution and eight drops of a urine specimen were boiled. The reaction showed no reduction. The urine specimen was sent to an out of town laboratory. A few drops of chloroform were added as a preservative. The report was positive for sugar. Will you please advise me whether presence of the chloroform was responsible for a positive reaction or whether it was due to decomposition of the urine or to both factors? What are other preservatives that can be used to avoid any possibility of false reports? Kindly omit name.

M D New York.

ANSWER.—In order to avoid decomposition of urine when it cannot be examined within twenty-four hours after being passed, many urinary preservatives have been recommended. But when not absolutely necessary it is better to avoid them. Urine kept in a cool place in a clean bottle can be examined even thirty-six hours after being voided.

The following preservatives have been used: salicylic acid, boric acid, chloroform, thymol solution of formaldehyde, camphor, chloral hydrate and corrosive mercuric chloride.

Chloroform added in small quantity to urine is a satisfactory preservative. But it must be known that its presence will lead to a pseudocarbhydrate reaction with qualitative Benedict's solution. The chloroform should be removed by heating the urine and then the tests are not affected. In the case cited, the chloroform was undoubtedly the cause of the pseudoreaction.

Three or four drops of solution of formaldehyde may be added for each pint of urine. This is an efficient preservative but it will lead to reactions simulating sugar and even albumin and also it forms a crystalline compound of formaldehyde and urea. Solution of formaldehyde also greatly interferes with the bile, urobilin and indican tests.

Thymol is a good preservative, but an excess may give a reaction similar to those for bile pigments, indican and albumin. The amount used should not exceed 0.1 Gm. for each hundred cubic centimeters of urine. Camphor, chloral and boric acid have been used, but they possess no advantages over the others. Boric acid may interfere with sugar determination. The examiner should be on his guard in reporting abnormal chemical action in a urine specimen to which a preservative has been added.

If it is desired to preserve a specimen of urinary sediment the best method is to add from 2 to 5 drops of a 5 per cent chromic acid solution. The only change will be a coagulation of the albumin into a granular material. It will preserve all the features permanently, not even causing any changes in the casts. Hayem's solution is also an excellent preservative for urinary sediment.

DENTAL CARIES

To the Editor—A certain family in my practice has three children, all of whom have teeth susceptible to early decay. The ages are 9, 8 and 6 respectively. They are representatives of the better class and their food is adequate in every respect. Only one indulges too much in sweets. Their teeth get constant personal and professional care. The mother has been advised by her dentist to use a proprietary combination of calcium phosphate and viosterol. As these children all drink an abundance of milk I have told her that this is useless. She wants to know what can be done to prevent bad teeth in her children. These youngsters are above average in health and nutrition although all three are asthmatic or potentially so. Is there any indication for calcium therapy when milk ingestion is ample? Could you suggest any method or treatment for this type of case?

JOHN HOWARD GREENE, M D, Slab Fork, W. Va.

ANSWER.—A large amount of scientific evidence has of recent years accumulated which indicates that dental caries is essentially a dietary deficiency disease. Experiments carried out in orphan institutions where the complete diet was strictly under control show that the frequency of dental caries rises and falls with the increase or decrease of carbohydrates in the diet. In a small percentage of children caries was completely inhibited, in approximately 90 per cent of all the children the caries prevalence was markedly reduced, and in only a small percentage of cases did diet, apparently controlled, manifest no inhibiting influence. In still other cases it has been shown that some children remain immune, no matter how unbalanced the diet.

An adequate diet should be diversified with a well balanced calcium-phosphorus ratio, along with a goodly amount of vitamins D and C.

While diet must be regarded as the one most important factor in susceptibility to caries it is by no means the only one. Others are heredity, the glands of internal secretion, mechanical factors and oral hygiene. The significance of heredity and the glands of internal secretion are today but little understood. Irregularly occluding teeth are more frequently carious than those in normal occlusion. Oral hygiene is important only as far as caries is concerned in those individuals who are sus-

ceptible. Whenever *Bacillus acidophilus* is present in the mouth, caries also is found, without its presence, caries is never found. Even the most careful mouth hygiene cannot completely prevent caries when conditions of the mouth are favorable to the existence of *Bacillus acidophilus*, but it can materially limit its activity. The condition that permits *Bacillus acidophilus* to live in some mouths and not in others is not known, but it is assumed to be systemic. The glands of internal secretions may, of course, be responsible, their abnormal as well as normal functioning may be affected by diet.

In regard to these three children, the diet should be knowingly and dependably regulated. This is difficult to do in private families. The diet should contain at least a gram of calcium daily. Alkaline fruits and vegetables should be given preference to acid cereals. In addition, the meal should be ended with some hard food substance to exercise the jaws and cleanse the teeth mechanically. Eating between meals, if any, should be restricted to fruits. If results are still unsatisfactory, the glands of internal secretion should be suspected. The fact that these children are actually or potentially asthmatic suggests disturbed calcium metabolism. The glands are again assumed to be responsible. The administration of calcium and phosphorus is of doubtful value if the diet is diversified; it usually contains ample amounts of these. The difficulty lies in the direction of improper assimilation.

POSSIBLE MOVEMENT OF CERVIX—INFECTION WITH GONORRHEA

To the Editor—1. Some years ago I knew a young woman who during coitus had the ability to rub the cervix uteri to and fro, anteroposteriorly against the male glands thus producing early orgasm. I have known of no similar case reported nor have I been able to find on inquiry among friends a like case. Is it unique? 2. On a certain day a man indulged in coitus with a woman who infected him with gonorrhea, as proved by his developing the disease after the ordinary incubation period. About twenty-four hours after the infecting contact the man had connection with a healthy girl. The result to this girl is not known to me. Did she possibly or probably contract gonorrhea? Please omit name.

M D

ANSWER.—1. During ordinary coitus the cervix makes various movements coming down to meet the penis, the external os opens and a suction action takes place to facilitate the entrance of the semen into the uterus. All this is purely reflex and involuntary. There are also many women, especially those of a passionate nature, who during coitus make all sorts of movements with the external genitals, but no instance has ever been recorded in which the woman could voluntarily move the cervix by itself either during coitus or otherwise. Either of the motions just described could easily be mistaken for such a condition.

2. As soon as a man is infected with gonorrhea, gonococci have entered his urethra, although it generally takes several days for these to multiply to sufficient numbers to cause the well known irritation and bring on the usual symptoms. But the gonococci are there at once after an infecting coitus, and it is more than likely that he would infect a third party even though his symptoms do not appear till much later.

LOW BLOOD SUGAR RECORDS

To the Editor—A patient of mine who took 55 units of insulin unwittingly at 6 p. m. and lapsed into coma about 9 o'clock was not treated until 11 when it required 70 cc. of 50 per cent dextrose intravenously to restore consciousness. Two blood sugar estimations by a competent technician were done on blood taken just before the dextrose was administered. Both readings were 14 mg. per hundred cubic centimeters. I am desirous of information regarding low blood sugar records and what the lowest record in the literature is. Please do not publish name.

M D Massachusetts

ANSWER.—Any data regarding low blood sugar records should be accompanied by a statement of the method used. In general, older methods yielded higher values because of non-sugar reducing substances (partly glutathione). Newer methods, largely by use of different protein precipitants, give values that are lower and represent more nearly the true dextrose content of the blood. It seems possible that in severe hypoglycemia the dextrose in the circulating blood may approach zero. In such a situation the blood sugar determination with certain colorimetric methods may give values that are about 20 mg. per hundred cubic centimeters or somewhat lower, although accurate colorimetric readings are usually not possible. Without knowing the type of method used in the case described, one may only suggest that possibly the "blood sugar" of 14 mg. per hundred cubic centimeters represented non-sugar reducing substances. Determination after fermentation with yeast might have settled this point. Blood sugars "too light to read" are not uncommon, and the literature contains at least one report of a blood sugar said to be zero.

NUMBNESS OF LIP AFTER OPERATION

To the Editor—In June 1931 I had an operation consisting of tonsillectomy and removal of polyps from the left maxillary sinus, the incision for the latter being made under the left side of the lip. Immediately after the operation I noticed an almost complete loss of sensation in the left half of the upper lip and in the left upper teeth. There was no motor paralysis of the lip. This condition improved slightly during the first year but I have noticed very little change in the last two years. The sensation I now have is difficult to describe but can best be characterized as a combination of numbness and hyperesthesia. For example food can collect between the lip and the teeth without my being aware of its presence there. I might add that the operation was performed by a very reputable man who specializes in this type of work. The point in which I am particularly interested is the ultimate effect of this condition on the teeth involved. My dentist has checked the teeth every six months since the operation and has found none dead but a much stronger electric current is required to produce a response in the teeth involved. I had roentgenograms made of these teeth two years ago and their condition was good at that time. In your opinion is there any chance for further nerve regeneration? Do you think that this condition will eventually necessitate the removal of these teeth? Please omit name.

MD Tennessee

ANSWER—The conditions described are doubtless due either to the operation or to the infection of the antrum probably the former. No criticism of the operator is implied, as this is an occasional complication of even the most skilful surgeon's work. Further improvement in sensation after three or more years is improbable. As to the teeth, the prognosis is wholly favorable. The nerve supply of the pulps is not entirely confined to a single group of nerve fibers and consequently it may be assumed that the teeth concerned are partially supplied with nerves. The life of the pulps of these teeth is dependent on an adequate blood supply and there is no reason to infer that this has been damaged in any way at all. There is no danger, therefore, that these teeth will have to be removed because of the postoperative complication described.

PREDOMINANT SEX IN HERMAPHRODITISM

To the Editor—In hermaphroditism does one sex always predominate and function while the other sex is rudimentary and incapable of function? Are there cases reported in which both sexes are rudimentary and incapable of function and vice versa?

BENJAMIN FLEISSIG MD New York City

ANSWER.—As a rule one set of sexual organs predominates and the opposite sex is rudimentary. As an example may be mentioned a large clitoris having more or less the resemblance of a penis while the other female organs are well developed. As an opposite example may be mentioned a small penis accompanied with a scrotum that is more or less bifid, resembling the vulva, while the penis resembles the clitoris. But all gradations have been reported, varying from both sets of organs being rudimentary to (rather unusual) both sets of organs being perfectly developed.

IMMUNIZATION AGAINST SCARLET FEVER

To the Editor—My own little girl, aged 7 had the five doses of scarlet fever toxin three years ago. This fall her Dick test shows a small area, 2 cm. of faint redness which I read as positive. Five years ago she had three doses of diphtheria toxin antitoxin. I gave her 1,000 units of diphtheria antitoxin thinking I had possibly exposed her from my clothing. This fall her Schick test was very much positive. 1 Should she have a repetition of the five dose scarlet fever toxin? 2 Is she apt to be protein sensitive to the scarlet fever toxin on second administration? 3 What is your opinion of the aluminum precipitate toxoid (one dose)? 4 I do not want so much repetition so will the one dose toxoid given during the five weeks necessary to complete the injections of scarlet fever toxin interfere with the development of immunity to either disease? 5 What can I tell my patients who inquire about the five dose scarlet fever toxin? I have been telling them that I think it worth the effort and expense but have recommended it rather guardedly.

H D KINSELL MD New Richmond Ind

ANSWER.—1 She should have further immunization against scarlet fever. This may be accomplished by injection of the first, third and fifth immunizing doses of scarlet fever toxin at intervals of one week, omitting the second and fourth doses.

2 There is no foreign serum in scarlet fever toxin. Occasional individuals, particularly those who have had diphtheria toxoid, are sensitive to proteins in the ordinary broth used in the preparation of the toxin. In such persons 0.2 cc of a 1:1,000 solution of epinephrine chloride taken up in the same syringe and injected with the toxin prevents disagreeable reactions.

3 The efficacy of the one dose of alum precipitated diphtheria toxoid is not yet established.

4 If the three doses of scarlet fever toxin suggested are used only two weeks will be required and it would be best to defer diphtheria immunization until after that period.

5 Some individuals retain immunity with greater difficulty than the majority and in these persons, as in the correspondent's daughter, it is usually found that there is a greater loss of immunity to diphtheria than to scarlet fever. The diphtheria as well as the scarlet fever immunization should be repeated. The tendency to loss of immunity in these individuals may apply also to smallpox.

Less than 10 per cent of persons immunized with the five doses of scarlet fever toxin lose enough immunity to require further immunization. However these persons never become susceptible to the same degree they were in the beginning so that if they received no further immunization and subsequently contracted scarlet fever the disease would not be as severe as it might have been without any previous immunization.

ROENTGEN THERAPY IN TERATOMA OF TESTIS

To the Editor—I have a patient who had pain in the left testicle beginning several days after a minor injury but too slight for concern. He was observed by several physicians for about ten weeks, no enlargement or other sign was noticed. He was finally given an Aschheim-Zondek test which was positive. A second positive test was made several weeks later and finally one year ago an orchiectomy was performed which was about four months after the first signs and without any preceding roentgen therapy. The pathologist's report was teratoma, no increase in size and no involvement of the scrotum or cord. Superficial and high voltage roentgen therapy was started about ten days following the operation, the lungs were not included. The patient suffered a severe reaction with pronounced gastro-intestinal disturbance which has been followed by a colitis persisting in date. There has been no other symptom or any abnormal condition. The patient has been greatly worried about his case especially during the first few months following operation. The Aschheim-Zondek test has been consistently negative. The patient lost a few pounds during the hospitalization and his weight has remained stationary. There is a difference of opinion as to the treatment of this case. The question arises whether or not further roentgen therapy should be given. Considering the negative tests and the noninflammatory nature of the lesion what extra consideration does the colitis involve? Please omit name.

MD Indiana

ANSWER.—In the absence of clinical evidence of disease, including roentgenologic examination of the lungs, and in the absence of a positive Aschheim-Zondek test, the consensus is that it is not advisable at this time to execute further roentgen therapy. There is some ground for difference of opinion on this position and some radiologists adopt the method of prophylactic irradiation at intervals over a long period in the absence of clinical recurrence. In this particular case the latter procedure is not advisable because the patient is apparently sensitive to radiation and developed a reaction following these treatments. Furthermore, if prophylactic irradiation is given in the absence of clinical evidence of disease, the areas that must be treated include such widely distributed sites as to render this procedure practically difficult to execute. Under the circumstances it is recommended that no radiation be administered at this time but that the patient be examined at frequent intervals, including x-ray films of the lungs and Aschheim-Zondek tests and that treatment be deferred to such a time as clinical evidence of disease arises or when the Aschheim-Zondek test shows an increasing amount of hormone in the urine.

LEAD POISONING

To the Editor—A local factory producing pigments is having trouble with lead poison, in spite of all the usual precautions being taken to avoid it. What would be the simplest and most accurate method for detecting minute amounts of lead in the blood of employees so that they might be moved to other parts of the factory before symptoms develop? Would spectroscopic examination of the blood of employees at regular intervals be practical? A high calcium diet causes deposit of lead in the bones while a low calcium diet with ammonium chloride favors its excretion. Would it be best for those necessarily exposed to lead but showing no symptoms to be on a high or low calcium diet during the time they are so exposed? In other words would it be better to attempt to deposit lead in the bones as it is absorbed by a high calcium diet or to attempt to eliminate it constantly by a low calcium diet? I will appreciate any reference to the recent literature covering these points. Kindly omit name.

MD Pennsylvania

ANSWER.—The best way to determine whether absorption of lead has occurred is to look for stippled red cells. For this a smear of blood should be fixed in methyl alcohol and stained with methylene blue either alone or followed by a light eosin stain by which method the red cells appear either greenish blue or light red, powdered over with fine blue-black granules which are sometimes clumped together. It is usually held that there should be more than 100 such cells per million to make a positive diagnosis and some authorities ignore anything under 500 per million but for an indication of the beginning of lead absorption the physician will do well to accept the lower figure.

For men constantly exposed to lead but showing no symptoms of plumbism the administration of a high calcium diet (especially in the form of milk) to encourage storage in the skeleton has the sanction both of long practical experience with this old poison and also of the newer experimental studies. ERUPTION ON AURICLE

To the Editor—May I trouble you for a little help in regard to a woman patient aged 24 who has an eczematous circle just back of the auricle? The inflammatory area is about 10 mm. wide and extends the entire length of the ear. Scales form and there is constant itching unless some remedy is applied to relieve it. Examination of the urine is negative. The general health of the patient is good except that she has some catarrh. An examination of the nasal passages was negative. She has some dandruff in the hair but not sufficient to be thought the cause of the eczema. All the usual remedies have been tried including ultra violet rays. I presume you would want further data for diagnosis but the fact is that all tests have been negative. It is now some three years since the area of redness appeared and it is constantly becoming more annoying. Kindly omit name.

M D, Ohio

ANSWER.—It is assumed that there is only one patch of itching, scaly dermatitis. It is referred to as a circle but this may mean only that it is oval, not clear in the center. The diagnosis rests in all probability between ringworm and lichen simplex. The scales should be examined for a fungus by soaking them for seventy-two hours in 10 per cent potassium hydroxide solution and examining with the high dry lens. If a fungus is found, half strength tincture of iodine should be applied once daily until irritation begins or until the stain becomes too evident, when Whitfield ointment, 3 per cent of salicylic acid and 6 per cent benzoic acid in ointment of rose water may be applied once a day.

If by a circle is meant a round or oval patch, the probable diagnosis is lichen simplex, kept up by rubbing or scratching. Only energetic measures will avail. X-rays and radium can be used only in the mildest dosage within the hairy scalp. Ultraviolet rays applied to cause vesiculation may be used, or graduated strengths of cresolic acid in alcohol, painted on once a week, in strength sufficient to cause scaling.

HOMOSEXUALITY AND MENTAL DEFECT AFTER ENCEPHALITIS

To the Editor—A boy now 14 who had encephalitis complicating pneumonia when a few months old and has failed to develop normally either mentally or physically, in the interval in spite of the best of attention and care is now showing a propensity to homosexuality. There now remains no doubt that during the past year he has engaged in the act not only with smaller boys but with men as well. Knowledge of the situation first came from some individuals he had solicited on the street and who knew him. His parents are now aware of his condition and are keeping him under complete surveillance having withdrawn him from school. What can be done with such a case from a medical and from a social standpoint? Where can I obtain reliable literature on the problem? Please omit name and address.

M.D. Tennessee

ANSWER.—It would particularly be important to know the degree of mental defect and in what way the physical development is lacking. One must not assume offhand that this boy is a true sexual invert. Being defective, he may accidentally have been inducted into homosexual practices. In his "Psychopathia Sexualis" (twelfth English edition, p 286) Kraft-Ebing describes how masturbators may acquire fondness for such practices, often on account of external circumstances, and a defective boy is more likely to do this. Homosexuality has been mentioned among the sequels of epidemic encephalitis, for instance by Rudolph Neustadt (*Die klonische Encephalitis epidemica*, Leipzig 1932, p 11). E. P. Bleuler (*J Nerv & Ment Dis* 71 361 [April] 1930) believes that homosexuality is curable in certain cases and the same opinion was held by the late Emil Kraepelin. Unless this boy is sufficiently defective to be eligible for the ordinary institution for defectives, he may possibly fit in the special institution for encephalitic behavior disorders described in a monograph by Earl D Bond and Kenneth E. Appell *The Treatment of Behavior Disorders following Encephalitis* New York, 1931. The boy ought to be examined by a psychiatrist with child guidance experience.

CHRONIC MICROCYTIC ANEMIA

To the Editor—I am at a loss to classify the type of anemia of the following case and would appreciate greatly any help. A quadriplegia, aged 39 complains of sore mouth weakness and some shortness of breath. The duration of these symptoms is indefinite, the onset having been gradual, but she thinks about one year. She has no sensory disturbances. The patient is very nervous and apprehensive about her condition. The positive changes on examination are lemon yellow color to skin smooth glossy tongue, lips very pale finger nail beds of poor color. Blood count showed hemoglobin 55 per cent (Dare) red blood cells 3,700,000 white blood cells 7,750 (patient menstruating). Smears showed polymorphonuclears 70 per cent single lobed neutrophils 3 per cent lymphocytes 15 per cent eosinophils 8 per cent, transitionals, 4 per cent. Erythrocytes showed microcytes present macrocytes present, poikilocytes present basophilic degeneration present 17 were reticulocytes found in two lengths of slide. Platelets seemed to be increased in numbers. A gastric examination was tried but the patient insisted that she could not swallow the tube. However since the time she has been on diluted hydrochloric acid her mouth is not so sore and she is able to taste her food better. Present treatment consists of diluted hydrochloric acid (15 drops with meals) and Ilextron (Lilly) four drops three times a day. Suggestions as to both diagnosis and treatment will be greatly appreciated. Kindly omit name.

M D Pennsylvania.

ANSWER.—The anemia appears to be of the iron deficiency type, such as occurs in women who have profuse loss of blood during their periods, but who, possibly because of a deficient secretion of hydrochloric acid have difficulty in utilizing the iron of their food. Each period causes an increased loss of blood without adequate restitution in the intervals. This type of anemia is sometimes called chronic microcytic anemia or idiopathic hypochromic anemia. Iron must be given in large doses (e.g., reduced iron, 0.5 Gm in capsules three times a day, after meals). Dilute hydrochloric acid (U.S.P.) may be given in 4 cc doses in a glass of water with each meal. If there is abnormal bleeding, the cause must be removed if possible.

POSTOPERATIVE RECURRENCE OF CYSTOCELE

To the Editor—I have observed early recurrence after an operation for a large cystocele. In quite a number of such operations I never had this experience. Is it difficult to find a cleavage plane between the vaginal wall and the bladder at a secondary operation? Is there any technical advice that I could use to advantage? Please omit name and address.

M D New York.

ANSWER.—Postoperative recurrence of cystocele is not common except following subsequent pregnancy and delivery. Recurrence is usually due to insufficient correction of an associated uterine prolapse. There is no fixed method for subsequent operations for its correction, and the type of operation to be performed depends on whether the patient is in the child bearing period or beyond the menopause. If in the former period, plastic repair should be done together with some type of internal shortening of the round and uterosacral ligaments. If the menopause has occurred an operation of permanence should be done. In case there is considerable prolapse, a Mayo vaginal type of hysterectomy and perineorrhaphy is the operation of choice. Should there be a large cystocele without much prolapse, a Watkins interposition operation should be performed, provided the uterus is of normal size.

DUPUYTREN'S CONTRACTURE

To the Editor—A girl aged 5 years was stricken with acute anterior poliomyelitis and survived with a rather marked residual paralysis of both lower extremities and with only slight atrophy of the muscles of the hands. After eight years the legs have shown no improvement but the hands have improved to the point at which the child learned to play the piano and could write quite well. At the age of 14 she was exposed to scarlet fever and a prophylactic dose of antiscarlatinal serum was administered by a physician who was not informed of the child's sensitivity to horse serum. No serum reaction was noted for the child contracted scarlet fever soon after the injection. After a stormy convalescence the fingers of both hands particularly the third phalanges were found to be spastically flexed in a clawlike fashion. This flexion has persisted, resulting in the child having to give up the piano and making writing very difficult for her. What from the facts stated might possibly have precipitated the present condition of her fingers? What is the prognosis? Kindly omit name and address.

M D New York.

ANSWER.—The history has some points of resemblance to Dupuytren's contracture. There may be fascitis, myositis or tendinitis.

There is evidently a postural, a toxic and a chemical factor involved in this case.

Any infection or chemical reaction may produce a contracture. Deformity is frequently the price paid for comfort during the acute stage of any illness.

The various factors in the treatment include adjustable splints, physical therapy including heat, massage and hot paraffin dips, and operations such as capsulorrhaphy or capsulotomy and tendon plastic procedures.

North Carolina June Examination

Dr Benjamin J Lawrence, secretary, North Carolina State Board of Medical Examiners, reports the written examination held in Raleigh, June 19 23, 1934. An average of 80 per cent was required to pass. Seventy-three candidates were examined, all of whom passed. Thirty-two physicians were licensed by endorsement after an oral examination. The following schools were represented:

Book Notices

Nutrition and Disease. The Interaction of Clinical and Experimental Work. By Edward Mellanby M.D. F.R.C.P. F.R.S. Consulting Physician Royal Infirmary Sheffield. Cloth. Price 8/6. Pp 171 with 65 illustrations. Edinburgh & London: Oliver & Boyd 1934.

This book presents the substance of a series of lectures delivered before the Royal College of Physicians in June 1933. It describes some of the problems that the author investigated while holding the combined laboratory and clinical post of professor of pharmacology, University of Sheffield, and consulting physician of the Royal Infirmary, Sheffield, England. The lectures attempt particularly to point out how the combined experiences of the laboratory and the ward or clinic interact in furthering medical science. With this end in view, the author shows how observations of disease in human patients have stimulated research on animals and how these laboratory observations have in turn been carried back to the ward for testing on human subjects. It is only through such mutual interaction, he believes, that the problem of nutrition in relation to disease can be solved.

Five main topics are covered in the lectures: (1) rickets, (2) dental structure and disease, (3) simple and toxic goiter, (4) nutrition and infection, and (5) nutritional influences on the nervous system. The report on rickets describes the author's early work in producing this disease experimentally in dogs, his discovery that cereals are rickets producing and that a fat-soluble vitamin is rickets preventing and follows the high spots in the rapid development of knowledge of this subject to the present time. Emphasis is given to the author's view that cereals, oatmeal in particular, contain an anticalcifying substance—a toxamin, which may be counteracted by calcium salts, by boiling the cereal in dilute acid or by vitamin D in any of its manifold forms. Reference is made to the finding by Gyorgi that maize has a more pronounced effect than oatmeal and to unpublished work of Bruce and Callow that phytic acid may be the toxic substance involved. Although this theory of an anticalcifying factor in cereals is not universally accepted, the majority of research workers believing that a deficiency of vitamin D, an unbalanced calcium phosphorus ratio or other factor interfering with calcium utilization is sufficient to account for rickets without postulating a toxic factor, the difference in point of view is of academic rather than practical importance, since both groups recognize that, whatever the fault, it may be corrected by including a source of vitamin D in the diet. To this Mellanby would add the restriction of the cereal intake.

The lecture on dental structure and disease presents in a brief fifteen pages the gist of Mrs. Mellanby's extensive investigations from 1917 to the present time on the factors determining tooth structure, incidence of caries and other dental disease, and practical methods for their prevention and control. Evidence is presented from laboratory work on animals and studies of human teeth to show that all types of faulty structure may be produced at will in animals by making slight changes in the diet, that there is a close correlation in human teeth between structure and caries—that is, that teeth of bad structure tend to be more carious than those of good structure and that the resistance of the teeth regardless of their original structure, may be increased by feeding diets good in calcifying properties, through building up of secondary dentin and that carious areas may even be arrested or healed by this means. Pyorrhea, moreover, may be induced or prevented by the absence or presence in the diet of determining dietary factors. The diet that produces normal tooth development and prevents or arrests caries is the same as that which prevents rickets, namely, one rich in calcium and phosphorus and vitamin D and low in cereals, while vitamin A is held to control the development of the gingival epithelium and a deficiency of this factor therefore, favors the development of pyorrhea. There is, of course, a whole school of workers who would present an entirely different theory of dental decay with evidence to support it—e.g. the one of which Bunting is a chief exponent. Again however, the disagreements are largely in respect to the mode of action rather than in the practical applications for the diets advised by the opposing schools for tooth protection are essentially the same.

The section on the thyroid reviews the history of thyroid physiology and especially the work of Marine and others on the relation of iodine to simple and toxic goiter. A summary of the experimental and clinical evidence from his own as well as other laboratories seems to the author to support the view that, although there is a close resemblance microscopically between simple and toxic goiters, their etiology is fundamentally different. "The simple goiter is due primarily to a deficiency of iodine in the body, whereas the toxic goiter is caused mainly by some mechanism pulling out the colloid with its active principles, as soon as it is formed into the general circulation and thus producing a local absence in the gland itself, and an excess in the blood. Both mechanisms produce thyroid hyperplasia. There is good evidence that the mechanism responsible for the withdrawal of the thyroid colloid involves a chemical substance in the anterior part of the pituitary gland. The deficiency of iodine which leads to simple goiter is primarily dietetic, especially in early life and the period of growth. The author presents evidence that has led to these conclusions and discusses their relation to the prevention and treatment of both types of goiter.

The discussion on nutrition and infection seems an unusually able and fair presentation of this debated subject. The author points out the difficulties involved owing both to inadequate methods of judging nutrition and to varied conceptions of what is meant by "infection." He shows how almost invariably workers with rats have demonstrated extreme susceptibility of vitamin A deficient rats to infections especially of the respiratory tract and the less clear-cut results in human beings. He points out that results as found in animals would not be expected in human subjects, because few diets even of the very poor are as deficient in vitamin A as are given experimental animals. It is known, however, that the poor, whose diets tend to be low in the protective foods, do have a higher incidence of the type of infection related to dietary deficiencies than do the higher economic groups. Clinical and experimental evidence from the author's laboratory and elsewhere is presented which shows that "in some infective disorders of the mucous membranes affecting human beings vitamin A raises the resistance and diminishes the incidence and severity of such disorders" (e.g. puerperal sepsis, measles). On the other hand, evidence is also given to show that "infection foci of the type seen in vitamin A deficient animals develop in human beings independent of the vitamin A reserves and therefore may have a different aetiological significance." The author believes very definitely then that vitamin A is one factor at least in the body's defense against infections, especially those involving epithelial tissues but he realizes also that there are other factors concerned, and he expresses himself as "prepared to use every available weapon which promises to lead to further knowledge."

The two lectures on nutrition and the nervous system deal with vitamin A in a newer role in relation to nervous disorders. It is shown through experimental evidence that widespread nerve degeneration results from a vitamin A deficiency and that nerve changes are found in xerophthalmia, night blindness and retinobulbar neuritis and may be the primary factor in these conditions and possibly also in other infective foci found in vitamin A deficient animals. The theory is also advanced that a vitamin A deficiency is wholly or in part responsible for the degenerative nervous changes found in a variety of diseases or conditions that were formerly attributed to other factors, namely, beriberi, convulsive ergotism, pellagra, lathyrism, and other conditions. In some of these as in ergotism and lathyrism a neurotoxin also is involved but vitamin A or carotene will prevent the changes and the accompanying clinical manifestations. The author admits that much additional work is needed to clarify this problem, but he believes that "the present work suggests not only a new field of possibilities in the way of treatment which is worthy of study but that in the diseases referred to above specific dietetic influences will prove to be of great importance certainly as prophylactic agents, and to a less degree as a curative means."

This book is an excellent concise presentation of the author's work and conclusions in a number of important fields of nutrition research. The conclusions expressed are in the main those commonly held by research workers, but some represent interpretations for which the author is at present the chief exponent.

As one reads through the entire text the points that stand out are the author's conviction that cereals have a definite antagonistic action in many aspects of human nutrition, and his strong belief in the dominating role assumed by vitamin A in the prevention of disease through its protective action both on the epithelial tissues and on the nervous system. The point of view and the supporting evidence should stimulate to further research in these fields.

Protoplasma Monographien Herausgegeben von R. Chambers und anderen. Band VII Pathologie der Mitose. Von Georg Lillitzer. Privatdozent der Embryologie an der Wiener Universität. Cloth. Price 16.20 marks. Pp 338 with 113 illustrations. Berlin Verlag von Gebrüder Borntraeger 1934.

A complete survey of the abnormalities occurring in cell division is contained in this monograph. The interest in the subject lies not only in the biologic aspect in that mutations are now being produced in large numbers in the fruit fly *Drosophila* by irradiation but also because it is undoubted that the action of x-rays, radium, cathode rays and ultraviolet rays is in part at least on the division mechanism of the cells. Certain of the theories of the origin of cancer which have been proposed in recent years assume that changes in the chromosomes may lead to the production of new races of cells, which possess the capacity of unlimited growth and large series of studies have been devoted to the investigation of the morphology of the mitotic figures and the number of chromosomes in cells of malignant neoplasms. All of this is excellently surveyed and the reader who wishes to extend his knowledge will find a useful and complete bibliography appended. There are also drawings, photomicrographs and charts.

Practical Surgery of the Abdominal and Pelvic Regions By James William Kennedy M.D. F.A.C.S. Surgeon in Chief to the Joseph Price Hospital Philadelphia. Second edition. Cloth. Price \$7.50. Pp 861 with 133 illustrations. Philadelphia F. A. Davis Company 1934.

This book was inspired by a student's love for his great master, Dr. Joseph Price, the author acting as an exponent of principles endorsed by his predecessor, particularly those which are at variance with the popular teachings. The chapters have been arranged in a haphazard manner, for instance a chapter on ligature and suture material is preceded by one on inguinal hernia and followed by one on surgery of ovarian cysts. The eulogy of Dr. Price is carried to extremes and includes a hyperbolic statement that "probably no operator living or dead was more the master of difficult and trying major abdominal work than Dr. Price." Some statements are contrary to the experience of other surgeons, others will be met with astonishment. Appendectomy in form of a stumpless removal of the organ is advocated irrespectively of the stage of peritoneal involvement, adhesions should be broken and the appendix removed in every instance, the author has probably an unrivaled record of "a good many thousands of appendectomies without a single death in cases where drainage was not necessary." He also established an enviable record of a mortality of 0.2 per cent after vaginal hysterectomy by the clamp method. The correctness of the statement that vaginal hysterectomy has the lowest operative mortality of any major operation will not go unchallenged. The author must be a second Houdini, as in 90 per cent of the cases he performs a vaginal hysterectomy in less than five minutes (p 15). He feels justified in promising a successful repair of the perineum in practically 100 per cent of the cases. On page 278 he says that no harm follows penetration of the rectum while repairing the perineum. According to his experience, the very ill patients from gonorrheal infection stand surgery well. The gangrenous gallbladder should be drained not removed. Trendelenburg's position, retractors and rubber gloves are tabu in abdominal surgery, absorbable material is never used, through and through sutures are employed as a routine for closure of abdominal incisions. Lest we forget the author reminds us countless times of his eleven years long apprenticeship with Dr. Price. The style and punctuation justify a suspicion that Gertrude Stein acted as a collaborator. A few quotations may corroborate this statement. The description of figure 32 reads as follows: "Fig 32 illustrates the popular method of tying the meso appendix which is incorrect in that it does not include the proximal vessels to the point of transfixion with a blunt instrument as a ligature carrier

such as the hemostat and thus the bleeding which might take place from the vessels which are not included within the ligature. The error is in the use of a blunt instrument such as a hemostat by which the ligature is carried through the meso appendix too far from the ceco-appendiceal angle which ligature does not include the most proximal vessels which are often the largest and nourish the proximal end of the appendix which becomes the stump of the incomplete operation." Practically every statement throughout the book is repeated several times. "Tubercular' is used instead of "tuberculous", "tenaculæ" instead of "tenacula", one finds such expressions as "the fibroid patient" (p 15), "the pathological surgeon" (p 105) or a sentence, "classify the lesion into operative and non-operative hours" (p 100), "I do not approve clamping any vessels if it can be avoided which later must be tied" (p 532). It is highly regrettable that such inexcusable shortcomings detract considerably from the value of the book which is exceptionally well illustrated and replete with interesting discussions.

L'épaule Anatomie des formes extérieures anatomie radiographique chirurgie opératoire Par Antoine Bassat professeur agrégé à la Faculté de Paris et Jacques Malaret Interne des hôpitaux de Paris. Paper. Price 65 francs. Pp 292 with 116 illustrations. Paris Masson & Cie 1934.

This book forms the second link in a series of monographs on normal anatomy and operative technic of articulations, the first being a monograph on the knee, a book on surgery of the ankle will soon follow. The first part of the book gives a thorough description of the normal appearance of the shoulder region as observed in the course of a clinical examination, and a detailed description of the roentgenographic appearance of a normal shoulder follows. This chapter is supplemented by an unusual and instructive feature in the form of drawings in which ligaments, tendons and muscles are sketched over roentgenograms. Finally, roentgenograms of injected synovial sacs and arterial trees are reproduced. The second part of the book is subdivided into several chapters discussing the most popular avenues of approach to the shoulder articulation, the treatment of penetrating wounds and suppurative arthritis, the surgical treatment of fractures of the upper portion of the humerus, surgery of dislocations of the shoulder, arthrodesis, surgical treatment of tuberculosis, ankylosis, intradeltoid amputation, and exarticulation of the shoulder. The monograph is complete well planned and not too verbose. The subject is presented in a clear, simple, concise manner. There are many beautiful roentgenograms, reproductions of photographs, diagrams and schematic drawings. The work is not a simple compilation of data, the authors carefully describe various methods in vogue but express their own views on many controversial subjects. Certain omissions have been noticed, for instance, the technic of local anesthesia has not been described as apparently it is not in favor with the authors. American literature received due consideration, e.g., Nicolas and Fowler's methods of operation for recurrent dislocation of the shoulder are discussed by the authors, generally speaking, however, bibliographic references are sadly inadequate for the amount of material covered in the text and there is no index of the literature. The book may be highly recommended to general and orthopedic surgeons, even those not well versed in the French language, as the illustrations talk for themselves.

Aids to Osteology By Philip Turner B.Sc. M.B. M.S. Consulting Surgeon Guy's Hospital London. In collaboration with N. L. Eckhoff M.B. F.R.C.S. Assistant Surgeon Guy's Hospital. Third edition. Cloth. Price \$1.50. Pp 222. London Ballière Tindall & Cox Baltimore William Wood & Co 1934.

The nomenclature recommended by the Anatomical Society has been adopted throughout this edition. It is about thirty pages longer than the preceding edition, and a revision of the text has been made by Mr. N. L. Eckhoff. The subject is treated under the headings of bones of the upper extremity, lower extremity spine and thorax, and skull. A description of each individual bone is offered, giving its location, shape, articulations and attachments of muscle and ligaments. This book, while devoid of illustrations, offers a useful and accurate guide to the student or practitioner in quest of descriptive information about the various bones of the skeleton.

Medicolegal

"Public Hospital" Defined—The defendant operated a hospital in Minnesota which she claimed came within a constitutional provision exempting public hospitals from taxation. The constitutional provision provided as follows:

Public burying grounds public school houses public hospitals academies colleges universities and all seminaries of learning all churches church property and houses of worship institutions of purely public charity and public property used exclusively for any public purpose shall be exempt from taxation.

During the year in question, 1931, the evidence showed that the hospital was conducted as an "open hospital," all physicians and patients being admitted on equal terms. The county sent to the hospital all patients who were public charges and paid therefor at a fixed rate. The hospital was conducted at a loss, although the defendant testified that she would not have refused to make a profit had it been possible. There were no charity beds in the hospital. A charge was made to all physicians for operating in the hospital and a regular charge was made to all patients. The defendant had full control and management of the hospital and had power to determine who should or should not be admitted and what doctors should or should not use the hospital. The trial court found that the institution was not a public hospital and the defendant appealed to the Supreme Court of Minnesota.

The word "public," said the Supreme Court, may be variously defined. It may be defined as meaning open for the use, enjoyment, and the participation of the public generally, even though a fee is charged as a public dance hall, a public carrier, etc. It may be defined as meaning owned by the public, that is, by the government or some of its subdivisions, as a public building, public court house, etc. It may in certain situations be defined as meaning operated for the benefit of the public rather than for the benefit of a private individual. It is quite evident continued the court from a consideration of the entire constitutional provision, that it was not intended to confine exemptions from taxation only to property owned by the public. It is unreasonable to suppose that mere access to, use of, or patronage by the public is the sole and only test of whether property is exempt under the provision of the constitution. In using the words "public hospital," the court said, the framers of the constitution and the voters meant first that there should be free access to the public without discrimination in order that a hospital may be a public hospital. It was further intended that a public hospital also should be operated for the benefit of the public in contradistinction to being operated for the benefit of a private individual, corporation or group of individuals. So construed, operated for the benefit of the public means operated without an intent to make a private profit. It is not thereby meant that the institution must dispense charity or that it may not charge a fee for services rendered. Operated for the benefit of the public does mean that the receipts shall not be substantially more than the disbursements, so that a profit results. The provision does not mean that a hospital is exempt for a particular year merely because there is no profit for that year. The controlling feature is whether the institution was built, organized and/or is maintained with an intent to make a private profit, not whether there happens to be a profit in any given year. Applying this definition to the case at bar, the court said that the defendant's hospital was not a public hospital. We will assume, said the court, that it was open to the public indiscriminately in 1931, but it was not operated for the benefit of the public during that year. The judgment of the trial court was affirmed—*State v. Browning (Minn.)*, 255 N W 254.

Malpractice Septic Arthritis Attributed to Negligent Treatment for Scarlet Fever—Two suits were instituted against the defendant-physician, one by the patient, a child, and the other by the patient's father, wherein it was contended that by reason of the defendant's negligent treatment for scarlet fever the patient developed septic arthritis and became permanently crippled. In each case a verdict was rendered for the plaintiff and the defendant appealed to the Supreme Judicial Court of Massachusetts.

The defendant contended, principally, that even admitting the truth of the plaintiff's evidence tending to establish negligence, there was no evidence showing the causal connection between the negligence and the patient's injury. The testimony taken as a whole, said the Supreme Court, was sufficient to warrant the jury in finding that the defendant knowingly was guilty of omissions in the care of the patient which would bring unnecessary suffering to him and would contribute to, if they were not responsible for, the patient's permanently crippled condition. The defendant concluded that he was negligent in administering the "antitoxin." He failed to instruct the mother, or other attendant of the child, to keep him on a milk diet and to give him plenty of water. He discouraged the removal of the child to a hospital and failed to call in a specialist or a consultant. He opened without the proper aseptic precautions abscesses that developed and in other ways did not do what good practice demanded. Although the jury might have found that no single act of the defendant proximately caused injury to the patient, the testimony warranted the jury in finding that the omissions of the defendant constituted improper practice from a medical standpoint and that they, in combination, caused to some degree injury to the patient. It was not essential to the defendant's liability, continued the court, that he should be able to foresee the precise manner in which the injury happened, it was sufficient that injury to another was reasonably to be apprehended as the result of the negligent conduct.

The Supreme Court, therefore, upheld the verdict in favor of each plaintiff, subject, however, to final action by the trial court on the defendant's pending motion in each case for a new trial on the ground of excessive damage—*Marangian v. Apehan (Mass.)*, 190 N E 729.

Insurance, Life Chiropractor Not a "Physician."—The plaintiff insurance company sought to avoid payment on a life insurance policy issued to the defendant's deceased husband contending that the insured was treated by a "physician" within the meaning of a clause in the application for the policy which provided, in effect, that the policy should not take effect if the insured was treated by a "physician" between the date of his medical examination and the delivery of the policy. During that period, the insured was treated by a chiropractor. From an adverse decision in the trial court, the insurance company appealed to the Supreme Court of Michigan.

The application blank, said the Supreme Court, like the insurance policy, was prepared by the insurance company and hence it should be read in terms most favorable to the insured. So read, the word "physician" must be held to mean a legally licensed physician or doctor of medicine. Such is the meaning that a reading of the application would convey to the ordinary lay mind. It follows that, concluded the court, notwithstanding the insured consulted a chiropractor and was treated by him between the date of the medical examination and the delivery of the policy, the insurance became effective on the delivery of the policy. The decree entered by the trial court awarding the defendant the amount due on the insurance policy was consequently affirmed—*New York Life Ins. Co. v. Modzelewski (Mich.)*, 255 N W 299.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1923 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk () are abstracted below.

Influence of Mucilaginous Substances on Emptying of Stomach.—Keeheles and his associates tested the effect of hog's mucin, okra, olive oil and agar on the motility of six normal subjects, six patients affected with peptic ulcer and a dog carrying both gastric and duodenal cannulas. While all the test substances decreased the emptying time of the stomach, okra had the greatest effect. At the beginning of digestion, hog's mucin increases and okra decreases gastric motility. After three hours this is reversed and okra diminishes the emptying time by 26 per cent. In the stomach okra does not impair the digestion of meat; it considerably decreases the amount of gastric secretion. The therapeutic significance of these results is discussed.

Bactericidal Power of Stomach.—Hansen shows that the bactericidal power of the stomach can be influenced by a number of factors. This property is enhanced by the taking of a meal one hour before the drinking of infected fluids. Meals with a high buffering value help to hold, and slowly give off, acid which serves to kill bacteria ingested one or more hours after the taking of a meal. In order that the bacteria may be killed it is important that the gastric contents develop an acidity as high as or greater than pH 2. After drinking contaminated liquids, the taking, within a short interval of time, of another

meal, perhaps well buffered and somewhat alkaline, will tend to wash living bacteria, left behind in the nasopharynx or esophagus by the infected meal, directly into the intestine. It has been found that banana pulp serves as a well buffered meal to hold hydrochloric acid in the stomach. The sterilization of the gastric contents can be influenced by the resistance which some foods show to acidification, that is, the so-called acid deficit. The authors' experiments were carried out on seven normal persons and on many patients, most of the latter ambulant, who were affected with minor disturbances, such as hay fever. The bacterium used was *Bacillus prodigiosus*, which was mixed with water or milk with a known buffer value and hydrogen ion concentration. Most of the foods used to influence the sterilizing power of the stomach were fruits.

Studies in Food Allergy.—The Oelgoetzes and Wittekind conclude from their study on sensitization to food that: 1. Most of the protein ingested is not split to the stage of amino-acids in the gastro-intestinal tract. A large part of the protein is absorbed into the blood as acid or alkali metaprotein and other derived proteins. The gastro-intestinal tract is essentially a receiving and mixing mechanism. Digestion is started in the gastro-intestinal tract but is continued and completed in the blood stream. 2. Normally, sufficient pancreatic juice is secreted to combine with all the food eaten and to provide an excess, which passes free (uncombined) into the blood stream, where it acts as a buffer solution, combining with and digesting any food that has been absorbed unmixed with enzymes. 3. Blood serum normally contains free pancreatic enzymes in a definite and constant concentration. These enzymes can be demonstrated by a test that the authors describe. 4. The concentration of pancreatic enzymes in the blood serum of a person on a regular ration, compared with that after taking a "test meal" consisting of quantitatively a greatly increased total ration, appears to be a direct measure of that individual's pancreatic (digestive) function. 5. It is probable that "hypersensitiveness" to foods is caused by an excess of free food (free of enzymes) in the blood serum, and that this excess is caused by a low pancreatic threshold (hypofunction). 6. In the authors' opinion the state of "allergy" to foodstuffs can be determined by ascertaining the concentration of free amylase in the serum before and after a test meal. 7. The rational treatment of sensitization to foods lies in the reduction of the total food intake. If the patient can maintain normal weight and adequate buffer enzymes on the reduced ration no other treatment is necessary. If he is unable to do so, it would seem that dry pancreatic enzymes must be administered to make up the shortage.

Treatment of Fibroids of Uterus.—Baer and his associates analyzed the case records of 1,001 patients treated for fibroids of the uterus during the last eleven years. No evidence was found to justify the conclusion that fibroids result from ovarian pathologic changes. Absolute sterility in this series was apparently due to tubal changes and not to the presence of fibroids or ovarian disturbances. Of the 1,001 patients, 73.5 per cent had one or more children and 80.4 per cent either had offspring

or had aborted, leaving an absolute sterility of only 19.6 per cent. Malignant conditions of the pelvis were found in 0.9 per cent, there being five sarcomas in fibroids and four carcinomas of the body of the uterus. The frequency of total hysterectomy shows an increase from 1.4 per cent in 1923 to 14.6 per cent in 1933. Vaginal hysterectomy shows a steady increase from 5.5 per cent to 18.1 per cent. Supravaginal hysterectomy remains the most frequently used treatment for fibroids, 56.2 per cent in 1923 as compared with 57.6 per cent in 1933. Myomectomy has its own group of indications. In the younger age group in which there are one or more children, it is being supplanted by supravaginal hysterectomy, 21.9 per cent in 1923, 7.6 per cent in 1933. The selection of radium as the treatment for fibroids has steadily diminished because of the increasingly long list of direct contraindications, the undesirability of a precipitate menopause, the inability to examine the pelvic and abdominal viscera and an appreciable proportion of failures, 11.1 per cent. Radium was used in 15 per cent of cases in 1923 and in 2.1 per cent in 1933. Partial or complete removal of the adnexa was performed in 47.1 per cent of the patients. Indications for these operations on the adnexa included not only pathologic changes but mechanical reasons and prophylaxis. The total mortality was 0.7 per cent (seven deaths). In the last group of 484 consecutive patients there was one death (0.21 per cent).

Blood Chemistry in Preeclampsia and Eclampsia—Stander and Cadden regard preeclampsia and eclampsia as the same disease. Their frequently repeated blood chemical studies in 108 eclamptic and forty preeclamptic patients showed that the blood chemistry is an indispensable index of the severity of the disease and of specific treatment needed. The nonprotein nitrogen content of the blood in eclampsia and preeclampsia remains within normal limits except in certain instances, late in the disease, when a rise indicates involvement of the kidneys as a result of the eclamptic disease. The blood urea nitrogen remains low, as in normal pregnancy, with the result that the ratio between urea nitrogen and nonprotein nitrogen is about 0.4, as compared with 0.5 in normal nonpregnant persons. The blood uric acid is increased in eclampsia and preeclampsia, indicating, the authors believe, a disturbance in its destruction in the liver. The uric acid content in the blood may be regarded as a fairly safe criterion of the severity of the disease. The blood sugar in eclampsia and preeclampsia is not greatly disturbed. Occasionally a definite hyperglycemia follows an eclamptic convulsion, owing perhaps to muscular activity. The alkali reserve is often decreased greatly, sometimes even to the level of true acidosis. The carbon dioxide combining power is the best and most readily available index of the necessity of antacidosis treatment. The blood chlorides are not decreased markedly, except in an occasional patient with marked edema. Blood thionine values in eclamptic patients are within normal limits. Glutathione is similarly within normal limits, except in patients with low blood hemoglobin readings. The increase in blood uric acid in eclampsia and preeclampsia cannot be accounted for by an increase in thionine. The hyperglycemia sometimes observed in the convulsive stage of eclampsia appears to be a true hyperglycemia and not due to glutathione or thionine.

Prevention of Impetigo Neonatorum by Use of Bacteriophage—Winder applied a stock solution of staphylococcus bacteriophage to the skin of the new-born in an effort to prevent impetigo neonatorum. Immediately following delivery and after the usual oil bath the entire surface of the infant's body (including the scalp) is washed with the bacteriophage. The aim is to assure a surface film of bacteriophage covering the entire body. This so-called bacteriophage rub is repeated on the fifth day, following the regular soap and water bath. The bacteriophage solution, being nontoxic and sterile, may be applied more often and probably should be repeated when an epidemic is in progress. Of fifty-six female infants receiving the treatment, no instance of impetigo contagiosa neonatorum has occurred. Of sixty-one male infants not receiving treatment there were twenty-one cases of impetigo contagiosa neonatorum. The use of staphylococcus bacteriophage as a surface wash for new-born infants appears to be a preventive of impetigo neonatorum.

Characteristics of Synovial Fluid in Arthritis—Keefer and his co-workers examined 120 samples of synovial fluid from ninety patients with various types of arthritis to determine the diagnostic significance of the various biologic and chemical characteristics of the fluid. 1. The bacteriologic examination of the fluids yielded information of the greatest value in the etiologic diagnosis of arthritis. Inoculation of guinea-pigs with the synovial fluid was helpful in the diagnosis of tuberculous arthritis. 2. The results of the gonococcal complement fixation and Wassermann tests of the blood and synovial fluids were in agreement. Both tests were of distinct aid in the etiologic diagnosis of disease of the joints. 3. The total cell count of the synovial fluid was increased in all the types of arthritis studied. It was highest in the infected fluids and lowest in the cases of Charcot joints and traumatic arthritis. Most noninfected fluids contained less than 40,000 cells per cubic millimeter. 4. When the synovial fluid was infected with micro-organisms the polymorphonuclear cells were greatly increased from 86 to 100 per cent and the lymphocytes, monocytes and clasmatocytes were few in number. In tuberculosis of the joints the polymorphonuclear count varied from 46 to 93 per cent and the lymphocytes and monocytes were increased. 5. The percentages of lymphocytes, clasmatocytes and monocytes were always higher in the noninfected than in the infected fluids. The presence of a low cell count with an increase in the monocytes, lymphocytes and clasmatocytes was an indication of a noninfected fluid. 6. The chemical examination of the fluids yielded no information of diagnostic value in discriminating

between infected and noninfected fluids. The nonprotein nitrogen of both the infected and the noninfected synovial fluids was the same as that of the blood. The sugar content varied with the presence of organisms, the number of cells and the level of the sugar in the blood. A low sugar content did not always mean an infected fluid. The total protein value of the synovial fluid was increased in both groups and indicated only an inflammatory reaction. Aside from the bacteriologic, cytologic and serologic examinations of the synovial fluid, other tests yielded little information of diagnostic value.

Myasthenia Gravis Associated with Thymoma—Because of the degenerative changes found in the suprarenal cortices in their two cases and in others cited in the literature and because of the reciprocal relationship that apparently exists between the suprarenal cortex and the thymus, Brem and Wechsler submit a new theory to explain the occurrence of thymomas in this disease: that the pathologic changes in the thymus are secondary to a degenerative lesion of the suprarenal. They believe this is supported by the following observations. The relationship between lesions of the suprarenal cortices and asthenia, such as occurs in Addison's disease and in chronic suprarenal insufficiency, needs no elaboration but that many such cases exhibit a hyperplasia of the thymus at necropsy is not well known. Following suprarenalectomy in the rabbit and rat, and less frequently in the dog and cat, there occurs a rapid and remarkable regeneration of the thymus, even in old animals. In infants, beginning about the second week of extra-uterine life, there occurs a spontaneous involution of the suprarenal cortex, coincident with a rapid increase in the size of the thymus. Finally, Marine assembled much evidence in support of the contention that status lymphaticus in man is dependent, in part at least, on a deficiency of some internal secretion common to both the suprarenal cortex and the gonads. The cortical extract that has been found to be efficacious in Addison's disease may not be the only hormone secreted, and in analogy to the pituitary syndromes, a derangement of another hormone of the suprarenal may be the causative factor in myasthenia gravis. The significance of thymic hyperplasia and thymomas in myasthenia gravis is still shrouded in mystery, but that some relationship does exist is shown not only by the frequency of their occurrence but by the good results reported in this disease following extirpation and irradiation of the thymus. The cardiac musculature in the authors' two cases exhibited the typical lymphorrhages which have usually been described as being present only in the skeletal muscles. Atrophy of the skeletal muscles was noted in one of the cases.

Adams-Stokes Syndrome with Transient Complete Heart Block—Weiss and Ferris report a case in which for ten years there were attacks of fainting precipitated usually by the swallowing of food. The patient had a traction diverticulum of the esophagus, distention of which with the aid of a rubber balloon promptly induced auriculoventricular dissociation of the heart and syncope. The release of pressure in the balloon was associated with a prompt return of normal sinus rhythm and the disappearance of symptoms. Barium chloride failed not only to influence the severity and the frequency of syncope but also to prevent the development of heart block. Epinephrine and ephedrine in small doses which induced no change in the arterial pressure and only slight elevation in the heart rate, abolished all the symptoms, although pressure on the diverticulum continued to induce complete heart block. Following the administration of epinephrine and ephedrine the onset of idioventricular rhythm, in contrast to the control observations, was associated with remarkably regular rhythm as a result of increased excitability of the ventricles. Atropine in doses that produced only slight depression of the vagal motor endings abolished the symptoms as well as the heart block. Paralysis of either of the vagus sheaths in the neck with procaine hydrochloride also abolished the fainting and the block. The Adams Stokes attack in this case was induced by heart block precipitated by a vagovagal reflex. The source of the reflex was irritation of the sensory endings of the vagi by the diverticulum. The intracardiac mechanism active at the onset and the disappearance of heart block of reflex origin are described. The cardiac output and other aspects of the hemodynamics in a case of complete heart block were studied with the acetylene

and optical methods. Ephedrine failed to induce a significant change in the blood flow. The relative part played by organic cardiac lesions and of neurogenic factors in the precipitation of Adams-Stokes attacks with heart block is discussed, and the simultaneous presence of multiple etiologic factors is stressed. Abnormal hyperactivity of the vagovagal reflex can be associated with a normal state of other reflexes of the same type. In the precipitation of Adams-Stokes attacks, cerebral ischemia due to decreased cardiac output is only one factor, other factors, particularly vasomotor reflexes, are emphasized.

Iodine in Treatment of Atherosclerosis—Rosenthal states that large physiologic doses of iodine in the form of inorganic potassium iodide or organic iodine bound intramolecularly with protein produced a marked increase of the cholesterol in the blood and liver and a corresponding decrease of the cholesterol in the bile in rabbits fed cholesterol. The hypercholesteremia thus produced was far beyond that of rabbits which had had cholesterol alone added to their diet. When iodine was added later in the course of cholesterol feeding, the cholesterol esters of the blood increased for six weeks. The author suggests that in the rabbits in which the cholesterol metabolism was so markedly disturbed the action of the iodine on a slightly active gland caused a regression of the gland and in doing so liberated an increased amount of the thyroid hormone. The latter stimulated the general metabolism as well as the liver. As the liver excretes only free cholesterol through the bile, there was a corresponding proportional increase of the cholesterol esters of the blood. The aortas of the latter animals presented the most marked lipid deposit, stressing the importance of the cholesterol esters in experimental atherosclerosis. A comparison of the thyroids of the animals fed iodine with those of the animals not fed iodine revealed a resting state of the colloid in the former and a slightly active state in the latter. As the action of iodine in the prevention of deposits of lipid in the aorta of the rabbit fed cholesterol is dependent on increased thyroid activity, its employment in man should be guarded.

Argentaffinomas of Gastro-Intestinal Tract—Bailey describes a series of thirty-one argentaffinomas of the gastro-intestinal tract and presents three cases in detail as representative of the various types of these tumors. The stroma of the argentaffinoma consists of collagen fibers, reticulum, nerve fibers, smooth muscle cells and elastica. A study of the elastic tissue shows it to be abundant in both the benign and the malignant type of argentaffinoma. The metastatic tumor has a stroma composed of collagen, reticulum and elastic fibers. The elastica is derived in part from the adventitia of the small and medium-sized blood vessels in the tumor. The argentaffinoma has the property of stimulating the production of elastic tissue, a characteristic rare among tumors. Intestinal obstruction results from the growth of the tumor in the serosal layer with consequent buckling and distortion of the tunica muscularis. Complete annular tumor growth did not occur. The author presents material to show that the argentaffinoma cannot be regarded as a paraganglioma of the sympathetic nervous system. Clinically, the argentaffinoma in any location except the appendix is characterized by its extremely asymptomatic course—throughout life if the tumor is benign, if malignant, until late in the natural history of the tumor. With location

in the appendix, the symptoms of acute or chronic appendicitis are simulated frequently. This is true whether the tumor is benign or malignant. The extremely slow growth of the tumor of the malignant type encourages radical resection even in the presence of metastases. The tendency of the tumor to grow in cords in the mesentery renders it advisable to resect a segment of mesentery even in the absence of gross invasion. Because of the asymptomatic course of the malignant tumors until late, few have been subjected to early operation. Of those that were, very few have recurred.

Allergic Inflammation of Lungs—Fried observed that, when an antigen is repeatedly injected subcutaneously into an animal its absorbing capacity diminishes with each subsequent injection. Moreover, in these cases the last injection (usually the fifth or sixth) produces an acute exudative inflammation locally, looked on as an anaphylactic phenomenon, it is assumed that it occurs as a result of a combination of antigen and antibodies. In the experiments reported, rabbits were sensitized by repeated intraperitoneal injections of horse serum, the last injection (defined as "shocking") being introduced into the lungs by way of the trachea. A study of the lungs of these animals showed that 1. The intratracheal ('shocking') injection of the heterologous serum soon produced an acute exudative rapidly spreading inflammation in the lungs. 2. In a high proportion of the animals studied the lesion at its height was confined to one lung having a diffuse lobar distribution. 3. The gross and microscopic aspects of the pulmonary lesion resembled in many ways acute lobar (fibrinous or genuine) pneumonia as seen in man. The nature of the latter disease was analyzed and the hypothesis arrived at was (in accord with the views of earlier observations) that in this malady the character of the lesion in the lung probably depends on a state of local pulmonary hypersensitiveness (allergy hyperergy). The author states that the similarities between the lesions in the lungs in genuine pneumonia in man and those that he observed in the experiments with horse serum (which he regards as model" infections) favor the foregoing hypothesis.

Mechanical Factors in Renal Infections—Mackenzie stresses the fact that any condition of the kidney or ureter which causes urinary stasis must be regarded as a factor in the etiology of infection of the renal pelvis. The obstructing

cause may be within the urinary tract or outside of it. The most common cause of obstruction within the urinary tract is stone. The most likely sites for lodgment of urinary calculi are at the ureteropelvic junction, at the brim of the bony pelvis and at the intramural portion of the ureter as it goes through the wall of the bladder. The obstructing cause may also depend on abnormality of development. Such abnormality may take place anywhere along the urinary canal, but it occurs more particularly in the upper portion where embryologic defects between the pelvis and the kidneys are so often found. Growths and inflammations in the neighboring organs may involve the urinary tract and thereby cause urinary stasis. Since the extensive use of radium in the treatment of malignant disease of the uterus and other pelvic organs, urinary stasis and infection sometimes have occurred from involvement of the lower ureteral segment in the ensuing cicatrization of the surrounding structures. Ureteral and renal pelvic dilatation and stasis have been demonstrated in normal pregnant women. Such dilatation the author believes, is physiologic but nevertheless is a definite invitation to renal infection. Not infrequently it has been found that renal stasis has been caused by an involvement of the ureter anywhere along its course in dense, calcified lymph nodes. By far the most common cause of obstruction in the upper ureter and pelvis is the sagging or ptosed kidney. The author stresses the importance of mechanical agencies in the etiology of renal infections, in nearly 13,000 admissions 36 per cent, or 4,688 cases, were diagnosed as definite renal conditions. Of all these kidney conditions 63 per cent were of the obstructive type—pyelitis, hydronephrosis, pyonephrosis, nephroptosis and nephropothesis with hydronephrosis—conditions the etiology of which lies in the mechanical obstructions or defects. A careful analysis of obstructive renal conditions confirms his early impression that the etiologic factors concerned in the production of such conditions have their incipience in early life. One twelfth of all the admissions were infants, children and adolescents up to 20 years of age.

Tumor Growth-Inhibiting Factor in Connective Tissue

—Morton and Beers point out that extracts from fresh normal human connective tissue (rectus sheath) exhibited a decided inhibiting action on grafts of rat tumor 256 transplanted into test animals. There was complete inhibition of tumor growth in 66 per cent of the animals and a marked retardation in the rate of growth in another 15 per cent the tumors in these instances being much smaller than the controls transplanted at the same time. In only one experiment was there failure to obtain a lasting growth-inhibitory effect. The tumors in these animals (19 per cent), although showing an initial retardation in growth, apparently overcame the restraint and at the end of five weeks were larger than the control series. Extracts from fresh normal human muscle tissue, on the other hand, showed no such inhibiting action on grafts of rat tumor 256

Poisoning Due to Shoe Dye—Harry reports four cases of poisoning as a result of contact with shoe dye. He presents a review of the available literature on this subject and gives the general train of symptoms and signs that usually accompany these cases. Symptoms characteristic of the poisons from the solvents used in shoe dyes are headache, dizziness, restlessness, backache, paralysis, convulsions, ringing in the ears, vomiting, dyspnea, weakness, nausea and methemoglobinemia. A constant sign is the intense cyanosis or bluish black discoloration of the skin, mucous membranes and nails. The author's cases were of a mild nature but serve to illustrate the point that in all cases of intense cyanosis poisoning from shoe dyes should not be overlooked.

Takata-Ara Test in Diagnosis of Liver Disease—Heath points out that the Takata-Ara serum reaction is not well known in this country and appears to deserve some recognition, not only as a diagnostic aid but also as an advance in the knowledge of the physiology of the liver. During the past year he has performed the test on the serums of more than 400 cases of all types entering the general hospital wards, par-

ticularly patients who showed evidence of liver disorder. The method used for testing the serum and ascitic fluid has been greatly simplified along the lines indicated by Crane. The author has found the Takata-Ara serum reaction to be positive in 60 per cent of seventy-seven cases of liver cirrhosis and also in certain cases of marked liver damage. It was positive in practically all cases of advanced liver cirrhosis. The reaction was positive in less than 3 per cent of 376 general medical and surgical cases in which there was no definite evidence of liver damage. The reaction is simple to perform and to interpret. It may be regarded at present as a specific liver function test, although it does not run parallel with other liver function tests. In particular it bears no relationship to the degree of jaundice. It is useful in the diagnosis of obscure abdominal conditions in which there is a question of liver cirrhosis or severe damage to the liver. Performed on ascitic fluid, it is of value in determining the presence of cirrhosis.

Use of Vaginal Antiseptics During Labor—In a study of the value of vaginal antiseptics employed during labor, Douglas and Rhees observed that both a 5 per cent solution of mercurochrome and a 1,000 aqueous solution of merthiolate are fairly efficient vaginal antiseptics during the first stage of labor. They decreased the colony counts with marked regularity and in a few instances there was at least complete temporary sterilization of the vagina. Metaphen in oil in the concentration employed is not an efficient vaginal antiseptic during the first stage of labor; the result being approximately the same as in the group of patients who received no instillation. In general the colony counts on poured plates were much higher

when incubated anaerobically than they were when incubated aerobically. In a considerable number of patients each had constant organisms in her series of inoculums in spite of instillations of the more efficient vaginal antiseptics. Carefully controlled experimental data, cultures being incubated under both aerobic and anaerobic conditions, are necessary to determine accurately the value of an antiseptic instilled in the vagina during the first stage of labor.

Undulant Fever—Within a radius of 45 miles, fifty-one patients having *Bacillus abortus* infection have been observed by Harris within eighteen months. Obviously, other cases exist in patients not ill enough to cause them to consult a physician or in those whose symptoms have been wrongly diagnosed when seen. No two of the author's patients had symptoms nearly identical. Among the frequent complaints are chills, sweating, indigestion, flatulence, constipation, nausea, vomiting, nosebleed, joint and muscle lameness, pain in various parts of the abdomen and chest, sore throat, hoarseness, cough, dysuria, loss of weight, anorexia, skin eruptions, palpitation and dyspnea. Little may be found objectively and thus a neurosis may be suggested. Usually the physical signs do not fit in with the tentative diagnosis. The diagnosis was made usually by the blood agglutination test. However, blood agglutination is negative in many instances early in the disease and, in a few cases, even after months or years. Low agglutination titers (1:10, 1:20 or 1:40) are as significant in patients with a clinical picture of undulant fever as is agglutination in dilutions of from 1:80 to 1:2,500. Repeated agglutination tests may be essential. In doubtful cases the skin test is of great value. Skin tests should not be done in patients previously treated with *B. abortus* vaccine, as violent reactions and local skin necrosis may occur. Treatment with *B. abortus* vaccine has been the only method showing real promise in these cases. Early infections appear to yield readily to vaccine therapy. Chronic infections respond slowly. The acutely ill patient does not tolerate any but the smallest amount of vaccine without severe or even violent reaction and, if circumstances warrant delay, should have no vaccine until the remission begins. Long standing cases may require much larger doses than the average full dose of 1 cc. Moderate reactions are apparently desirable, especially in long standing cases in which there may be assumed to be foci of infection in tissues not easily influenced by stimulation of antibodies. Relapse often occurs during treatment or after it has been discontinued and is usually attended by a sharp rise in agglutination titer, which subsequently falls as improvement occurs again. Forty-five patients have been discharged as apparently cured after a minimum of six weeks and a maximum of ten months of treatment and have remained well for periods up to one year. The remaining cases were of long standing before treatment was begun, the history in some indicating from five to ten years of infection and in one probably nineteen years. These patients have all improved markedly under treatment.

Distribution of Immunity Against Encephalitis Determined by Serum Protection Tests in White Mice — Wooley and Armstrong carried out serum protection tests in mice on 524 human serums collected from forty-nine cities located in twenty-six states and the District of Columbia which gave definite protection in 158, or 30.1 per cent questionable protection in 56 or 10.7 per cent, and no protection in 310, or 59.1 per cent. Serums giving definite protection were collected from thirty-two cities located in twenty-one states and the District of Columbia. Of serums from thirty-nine cases of clinically definite encephalitis from the St Louis epidemic (1933), collected from four to ten months following the attack, thirty-seven, or 94 per cent, showed protection. Among 113 normal controls having no known exposure to encephalitis there were eleven, or 9.4 per cent, whose serums gave protection, while among fifty-six normal controls who had been in contact with cases there were twenty, or 35.7 per cent whose serums showed definite protection. A positive serum protection test is believed to be evidence that the serum donor had been in contact with the virus of encephalitis and had suffered either a clinical or a subclinical type of infection. The authors believe that the serum protection tests that they report indicate that the St Louis (1933) type of encephalitis is immunologically distinct from epidemic encephalitis, poliomyelitis and the post-infectious encephalides.

*Observations on Peptic Ulcer Experiments Indicating Etiologic Importance of Chemical and Mechanical Factors and Their Relationship to Pyloric Dysfunction C B Morton University Va —p 316

Observations on Peptic Ulcer—Morton discusses experiments which seem to suggest that the pylorus plays an important part in controlling the chemical and mechanical factors which are commonly thought to be of importance in the etiology

of peptic ulcer. The results of the experiments, in which a degree of alteration in the normal function of the pylorus has been produced by encircling the pyloric ring with a contractile band of jejunal muscle, seem to indicate that primary pyloric dysfunction may cause chronic inflammatory lesions of the duodenum, probably through a disturbance in the normal acid-alkali relationship and balance at the pylorus. In the dog the lesion is a duodenitis that is almost identical with duodenitis in man. Because of the definite relationship between duodenitis and duodenal ulcer clinically, the probable significance of the results as regards the etiology of peptic ulcer in man is suggestive.

Sporadic Hemophilia and Its Therapy—Marr and Herrmann cite two sporadic cases of hemophilia. They believe that a reliable and effective treatment, constantly available, consisting of the intramuscular injection of whole blood and blood taken from the patient himself, combines the effect of venesection with that of injected blood. They also believe from the results of the blood studies observed following the injection of whole blood that the decrease in the coagulation time can be explained on the basis of the increased platelet count, and it seems conceivable that these new platelets must be less resistant to disintegration and therefore more likely to promote a quicker coagulation of the blood. Between periods of bleeding to promote general health, to prevent infection and to maintain the clotting element at the highest possible level a high protein, gelatin and high vitamin B diet is indicated. The use of protein sensitization is effective if followed continuously, but care must be exercised not to produce a generalized protein reaction. Good results may be obtained by the use of estrogenic substance in some cases. The causes of sporadic hemophilia are not known, but congenital syphilis is occasionally accompanied by this condition. Other causes may be operative such as the absence of estrogenic substance. This possible etiologic factor remains to be established. In this manner the authors' second patient, conceived at the end of a long family and during the onset of the mother's menopause, seems worthy of comment.

Effect of Diet of Dextrose on Fluid Balance of Body—Byrom states that during the last two years a number of diabetic patients have been restricted, for therapeutic reasons to a diet composed of pure dextrose dissolved in distilled water, for periods of from five to ten days. The daily intake of dextrose varied in different cases, between 480 and 600 Gm, administered in equal doses every hour or every two hours throughout the twenty-four hours. Insulin was given simultaneously in sufficient quantity to prevent, in most cases glycosuria or ketosis. The subjects were for the most part confined to bed and were allowed to drink extra distilled water at will. In some instances the patient was at first restricted to a fixed balanced diet, isocaloric with the dextrose diet, for a preliminary period of several days. This exclusively carbohydrate diet caused invariably an immediate loss of body weight amounting to several pounds. A sudden loss of weight of this degree in the face of an adequate caloric intake of 2,400 calories daily, is likely to be due, substantially, not to destruction of body tissue but to loss of body fluid. It was found that this change was accompanied by a parallel loss of electrolytes (sodium and potassium) from the body in amounts which indicate that the loss of weight is due largely to depletion of the extracellular (water + sodium salts) and intracellular (water + potassium salts) compartments of the body fluid. The extracellular loss of fluid was caused by the sudden curtailment of the intake of sodium. Similarly the intracellular loss may be attributed primarily to potassium restriction. Destruction of protoplasm to yield protein may play a subsidiary part.

Influence of Diet on Sugar Tolerance—Himsworth found that in normal human subjects the diminished dextrose tolerance and impaired sensitivity to insulin observed when the subject is taking a high fat diet do not depend on a change in the pH of the blood to the acid side, and that the improved dextrose tolerance and increased sensitivity to insulin found in subjects receiving a high carbohydrate diet are unassociated with a change in the pH of the blood to the alkaline side. The reaction of the blood was found to be the same on either diet. The production of a compensated alkalosis in a subject on a high fat diet resulted in no improvement either of the impaired sugar tolerance or diminished sensitivity to insulin. The presence of a compensated acidosis had no deleterious effect

on the increased sugar tolerance and insulin sensitivity characteristic of the high carbohydrate regimen. In normal men the presence of a ketosis had no effect on either the dextrose tolerance or the sensitivity to insulin. The administration of raw liver to a subject balanced on a high fat diet produced no change in dextrose tolerance or insulin sensitivity. The daily oral ingestion of 25 Gm of lecithin for a period of one week, to a subject standardized on a high fat diet, caused little or no change in the dextrose tolerance. Ten days after cessation of the lecithin administration a small delayed improvement in tolerance appeared to have occurred, although the subject continued to receive the same high fat diet.

Effect of Food, Gastric Distention, Temperature and Exercise on Angina of Effort—Wayne and Graybiel observed the relationship of pain in cases of angina of effort to the taking of food, gastric distention, external temperature and repeated exercise. They found that an average reduction of 25 per cent in exercise tolerance occurred after a heavy meal in six cases of pure angina of effort. In the same six cases, exercise tolerance was unaffected by inflation of the stomach with air, even when sufficient air was introduced to give epigastric discomfort and to displace the heart. It is concluded that in angina of effort the reduction of exercise tolerance after food is due to the increased energy expenditure of the heart and not to gastric distention. In normal subjects, large amounts of air were introduced into and retained by the stomach. While the stomach was distending, slight changes in pulse and blood pressure occurred, but, when the stomach had adapted itself, no changes in the cardiovascular system could be detected, even though the heart was displaced mechanically. In a case of spontaneous angina in which both food and gastric inflation gave rise to attacks, it was considered likely that distention of the stomach may initiate reflexly an attack in this type of case. Variations in the external temperature did not affect exercise tolerance in six cases of angina of effort. Two types of angina of effort exist, in both, exercise tolerance is constant if sufficient rest is allowed between the end of one attack and the start of the next test. In one type, as this period of rest is reduced exercise tolerance diminishes gradually, in the other there is a phase which may be as long as an hour, during which exercise tolerance is increased. Diminishing the rate of exercise had in two cases no effect and in four gave a moderate increase in the total amount of exercise performed. In a case in which the symptoms resembled those described under the term "angina sine dolore," investigation showed that the attacks were due to paroxysmal ventricular action brought on only by exercise.

Angina Pectoris and Intermittent Claudication in Anemia—Pickering and Wayne point out that pains clinically indistinguishable from those of intermittent claudication and angina pectoris may occur in any type of severe anemia. Of twenty-five consecutive ambulatory cases of severe anemia, there was pain in the legs in seven and pain in the chest in eight, induced only by exercise and relieved by rest. After cure of the anemia only one patient experienced pain in the legs and two pain in the chest. In nine grossly anemic patients, exercise of the limbs without circulatory arrest produced severe pain having the characteristics of intermittent claudication. After cure of the anemia, similar exercise produced slight or no pain. After a given amount of exercise, the flow of the blood through the active muscles is at least as great in the anemic as in the nonanemic state. The authors suggest that the stimulus which produces the pain of intermittent claudication is an accumulation in the tissue spaces of metabolites removed normally by oxidation. In six severely anemic patients, complaining of sternal pain or tightness on walking, the sensation was reproduced by exercise tests. In four patients the same exercises no longer produced pain or tightness when the blood contained more than 50 per cent of hemoglobin. In two patients the exercise tolerance increased with a rising hemoglobin content of the blood, but pain could still be induced when the blood was normal. The reaction of the rate of the heart and blood pressure to exercise is usually altered in anemia, and such alterations may contribute to the development of anginal pain. The essential factor in the production of anginal pain is a diminished oxygen supply to the working cardiac muscle. The authors' observations support the view that angina pectoris and

intermittent claudication are due to similar mechanisms operating in the cardiac and skeletal muscles. Reasons are given why some, but not all, anemic patients complain of angina or of intermittent claudication. No electrocardiographic changes characteristic of myocardial anoxemia were detected in anemic patients after exercise. In two cases the PR interval was abnormally long in the anemic state and was within normal limits after the anemia was cured.

Molluscum Contagiosum. Preliminary Note on Treatment. L. M. Ghosh—p. 630

Molluscum Contagiosum.—Accepting the theory that molluscum is conveyed by a filter-passing virus and that the infection is a local one, the virus being confined to the molluscum nodules, Ghosh prepared a vaccine by emulsifying a nodule and killing the virus by formaldehyde. The result of the injection of this vaccine was encouraging, and the result has been uniformly successful in all the cases tried so far. About a fortnight is required for the complete cure, but improvement is noticed after ten days, i. e., after the third or fourth injection. The nodules first shrink, then dry up and drop off by themselves. No relapses have occurred as yet, although six months has elapsed with many cases. The author has not been able to determine whether an autogenous vaccine, prepared from the patient's own nodules, is more beneficial than a stock vaccine prepared from the nodules of other patients. In preparing the vaccine the skin is sterilized with a mixture of equal parts of ether and alcohol, and two or three nodules are cut off with sharp scissors. The nodules are collected in a small sterile test tube previously weighed in a fine balance. About 20 mg. of nodules is required. Freshly prepared sterile physiologic solution of sodium chloride is measured in a sterile test tube in the proportion of 1 cc. per milligram of nodule. The nodules are ground well with sterile pumice stone powder or fine sand in a sterile agate mortar until the emulsion is uniform and no tissue is felt or seen. The sodium chloride solution is added at intervals in small quantities. When the emulsion is completed the remainder of the solution is added. The emulsion is then filtered first through krysolgar and then through an L. 3 Chamberland fine bacterial filter candle. The filtrate is incubated for twenty-four hours and tested for sterility. This forms the stock active emulsion. Of the stock active emulsion, 2 cc. is added to 8 cc. of formalized saline solution again tested for its sterility, and the vaccine is ready for injection. Intra-

dermal injection is given every third or fourth day, beginning with 0.1 or 0.2 cc. and increasing by 0.1 cc. or 0.2 cc. each time, according to the reaction.

Brain Tumors in General Practice.—To determine what were the first signs that made the physician in charge suspect a tumor of the brain, McConnell has reviewed his case notes. The signs that in his cases have aroused the physician's suspicion of intracranial tumor have been headache of any type especially in the morning, vomiting that did not materially interfere with appetite, epileptiform attacks, ranging from a transient "lapse" to full fledged convulsions, changes in mentality, retardation of growth, failure of vision, "queer feelings" in the limbs, and noises in the ear. Headache, vomiting and papilledema are the three cardinal manifestations of increased intracranial pressure. The patient can tell about the headache and vomiting, but he knows nothing of the choked disk, so that unless those symptoms suggest something to the physician the latter will not examine the optic disks, even if he is able to do so. It must be emphasized that it is papilledema not failing vision, that is the classic sign of increased intracranial pressure, therefore papilledema must be looked for.

Test in Tuberculosis of Kidney.—McGrath outlines a test for the determination of the relative efficiency of each kidney. It consists of the gravimetric determination of the specific gravity of urine collected from each kidney through ureteral catheters. The test is especially helpful in cases of renal tuberculosis. The urine is centrifuged as soon as it is received. This throws down the formed elements that would cause errors in the determination of the specific gravity and the sediment can be used to examine for pus and for tubercle bacilli. The supernatant urine is then pipetted into the specific gravity bottle. The bottle is stoppered, wiped and weighed. It is then emptied and is weighed again when filled with urine from the other side. It is lastly weighed full of distilled water. The difference in weight is due to the higher specific gravity of the urine. As large a bottle as possible is used, as liability to error is less.

Agranulocytic Angina.—Fisher presents two cases of typical agranulocytic angina that were admitted to the hospital as cases of diphtheria. The first patient was found to have a terminal pneumococcal septicemia. Agranulocytic angina developed in the other patient while in the hospital. Although suffering from diabetes, her condition was good and she was getting up each day. While there she had one tablet of allylisopropylbarbituric amidopyrine daily for seventeen days and 5 grains (0.3 Gm.) of soluble barbitol for two days. Her

symptoms commenced on the seventeenth day, when she was transferred to another hospital. Apart from an occasional tablet of acetylsalicylic acid, she had taken no drugs prior to this. In the first case no drugs of any kind were being taken prior to the onset of symptoms. It therefore belongs to that category of cases in which no etiologic factor can be determined. The author was unable to obtain pentnucleotide in time for treatment, as both patients died fifteen and twenty-three hours, respectively, after admission. Both patients showed a complete absence of polymorphonuclear leukocytes and few myelocytes but numerous myeloblasts. The changes found were similar to those described by Fitz-Hugh and Krumbhaar, who put forward the hypothesis that the myeloid hyperplasia is due to a primary maturation arrest rather than to a 'primary aplasia' and pointed out certain analogies to pernicious anemia. In hemorrhagic purpura the bone marrow may show either megakaryocytic hyperplasia or aplasia. Hubble suggests that there is one variety of agranulocytic angina and one variety of hemorrhagic purpura allied to aplastic anemia, for in all three the formation of blood cells is arrested at the reticulo-endothelial stage by the absence of certain factors. The other varieties are comparable to megaloblastic anemia. In this last there is a circulating anemia in spite of proliferation of the megaloblast hyperplasia of the megakaryocytes with a peripheral thrombocytopenia, and a myeloid hyperplasia with a peripheral agranulocytosis.

Weil's Disease in Northern Queensland—Cotter and Sawers present the laboratory and epidemiologic observations of the Ingham epidemic of infectious jaundice. In discussing the problem of prevention they state that the combination in the Ingham district of moist conditions favorable to the existence of leptospirae, the presence of rats in great numbers and an industry that necessitates exposure of the workers raises a problem of great difficulty. The excess of water is intermittent and the nature and area of the country render drainage impracticable. In the Ingham area the rat may be of particular importance, as the flooding of the land is intermittent and but for reinfestation of the water the problem would not be so acute. The conditions in the cane areas are extremely favorable for rats, food and cover being plentiful. The destruction of rats is undoubtedly advisable, but an inspection of the country shows the magnitude and difficulty of the task. The persistence of leptospirae in the urine of human convalescents raises the question of the danger of human carriers, although there is little evidence that human carriers play an important part in the spread of the disease. In the Ingham outbreak there has been no evidence of spread by human carriers. General measures to prevent access of the organism to the mucous membrane of the mouth and to abraded skin are advisable, but the nature of the work of cutting cane and the climatic conditions render satisfactory application difficult. It is probable that persons recovered from the disease possess considerable immunity, and this naturally acquired active immunity may tend to decrease the incidence of the disease in the district. Artificial active immunization has been successfully attained in laboratory animals and with further investigation may prove a possible means of prevention in man.

Blennorrhagia and Pregnancy. Astrinsky and Grinner—p 430

Hormone Therapy of Amenorrheas—Tschertok believes that many of the failures reported in treating amenorrhea by hormone preparations are due to insufficient analysis of the individual character of the amenorrhea. He divides amenorrheas into five groups and discusses the possibilities of hormone treatment for each. In the first group amenorrhea results from changes of the uterine mucosa, the ovaries remaining normal. Here there are no indications for hormone therapy. In the second group amenorrhea results from insufficient ovarian function with normal function of the anterior lobe of the hypophysis. Here hormone therapy must consist in the introduction of the missing ovarian factors. Estrogenic substance is to be recommended; the author obtains good results by the use of the urine of pregnant women in the last months. In the third group amenorrhea results from insufficient functioning of the anterior lobe of the hypophysis. Here alternating injections of anterior pituitary-like principle and estrogenic substance are recommended. The fourth group, which results from an excessive functioning of the follicular apparatus, is wholly unaffected by hormone therapy. In the fifth and final group, amenorrhea is the result of general causes. If hormone therapy is employed, it should be combined with other measures aimed at improving the general condition. Thus, he believes, hormone therapy requires patience and months of observation after each case has been carefully studied and classified, the proper therapy instituted and the dose individualized.

*Leaving Uterus After Bilateral Salpingo-Ovarectomy. H. Costantini—p 1878

Leaving the Uterus After Salpingectomy—Costantini deplors the systematic removal of the uterus when it is merely necessary to remove diseased adnexa. He questions the rationale of performing a subtotal hysterectomy because it is easy and leaving the cervix in place when it is that portion of the uterus which is most dangerous. He believes, however, that leaving the uterus in the presence of bilateral salpingitis possesses the following advantages: 1 The pelvic equilibrium is preserved. 2 The menstrual periods reappear in from 30 to 40 per cent. 3 Auto or thoracoplastic ovarian graft becomes possible and raises the percentage of menstrual period restorations to perhaps 70. 4 The functional disorders of the surgical menopause are less frequent and less serious than those following hysterectomy.

*New Anti-Infectious Therapy. Carbon Intravenously. A. Touraine and B. Menetrel—p 1997
Treatment of Toxicomanias by Emulsion of Vegetable Lipids. R. Dupuy and M. Delaville—p 1998

Treatment of Infections with Intravenous Injections of Carbon—Touraine and Menetrel, after using animal carbon with some success, tried the vegetable carbon, which is not a wood extract. This has a good absorbing power and possesses an electric charge in gamma rays which may be photographed. This carbon calcinated at a high temperature in contact with metallic vapors, was carefully neutralized, ground, pulverized and suspended in a 2 per cent solution of sodium chloride. The action was compared with that of animal carbon on the rabbit and then on man. The activated carbon seems to be better tolerated than the animal carbon. The anti-infectious action was tested in the rabbit without definite results. Some rabbits infected with cultures of staphylococci were more resistant after having received injections of carbon, but definite cures were obtained in only four of twenty cases. In some cases of human suppurative conditions, the results of carbon injections were more favorable. The injections are not painful and produce no early or late inflammatory reactions. The authors believe that the method of treatment is promising.

Prensa Medica Argentina, Buenos Aires

21: 2149-2196 (Nov. 14) 1934

- *Liver Function in Pulmonary Tuberculosis A. A. Raimondi and W. d'Amato—p. 2149
Pulmonary Murmur in Echinococcosis of Lung J. J. Beretervide—p. 2156
Typhoparatyphoid Agglutination After Oral Immunization R. F. Vaccarezza, L. M. Martinez Dalke and A. J. Vaccarezza—p. 2160

Glioma of Retina Case B. Just—p. 2180

Liver Function in Pulmonary Tuberculosis—Raimondi and d'Amato state that hepatic insufficiency is commonly observed in patients having pulmonary tuberculosis. They observed the liver function especially the chologenic function in twenty-two patients; four had tuberculosis in evolution, thirteen active tuberculosis and five arrested tuberculosis. The four patients of the first group had clinical and functional symptoms of liver insufficiency and slight allergy; a cuticreaction of one plus in one patient, of two plus in two and of one plus-D in one. In three patients of this group, the hepatic function was diminished. Seven patients of the second group had functional and clinical symptoms of liver insufficiency, diminished hepatic function and allergy resembling that in patients having tuberculosis in evolution; that is a cuticreaction of one plus in two patients, two plus in two and one plus-D in three. The remaining six patients in this group did not show symptoms of liver insufficiency. Nevertheless the liver function was partially diminished and they had a better condition of allergy than did those of the subgroup of the same group; that is, a cuticreaction of one plus in two and of two plus in four patients. The hepatic function of the patients having arrested tuberculosis was better than that in the patients of the previously mentioned groups and the allergy was more intense; that is a cuticreaction of three plus in all patients of the group. Generally speaking there is a parallelism between the activity of the tuberculous lesion and the involvement of the liver function, which may serve as a prognostic datum. The study of the biligenic function is important in relation to the nutrition of tuberculous patients, since bile favors digestion, and above all the absorption of fats, owing to its zymogenic action on digestive ferments and stimulating action on the secretion of pancreatic juice. Bile also has a stimulating action on the motor functions of the duodenum and rectum, the movements of intestinal villi, the circulation of chyle and intestinal evacuation.

Mean Intraventricular Pressure During Ejection Phase J. Duomarco—p. 281
Mean Arterial and Mean Intraventricular Pressure J. Duomarco and R. Piaggio Blanco—p. 287

A Sign of Aortic Disease—Gonzales Sabathie says that the verification of blood stasis of the left external jugular vein (either predominant, if bilateral, or exclusive if unilateral) is in most cases a sign of aortic disease. He found the sign in patients suffering from any of the following aortic diseases: (1) arterial hypertension associated with aortic alterations, (2) aortitis, (3) aortic sclerosis and (4) aortic aneurysm. The sign is so noticeable in some cases that it may be observed with the patient dressed and in the standing position. When it cannot be seen in these conditions in patients suspected of being sufferers of aortic disease, it may be clearly noticed during deep expiration when the patient is placed in the dorsal decubitus with uncovered neck and the head turned to the right. Because of the intimate anatomic relations between the left innominate vein and the higher point of the aortic arch, the blood stasis of the external jugular vein may be interpreted as caused by a compression of the former by the latter due to a pathologic lengthening of the aorta. The fact that the presence of the sign coexists, in most cases with an increased venous pressure and a decreased velocity of the circulation in the left side seems to make the pathogenic interpretation of the sign more plausible.

Diagnostic Sign of Complete Auriculoventricular Block.—Cossio and Lascalea describe a sign of diagnostic

value in complete auriculoventricular block. It is an occasional third heart sound occurring early in diastole, immediately after the second sound in such a manner that it may be interpreted as a reduplication of the latter. It is heard by auscultation of the heart region from the left third costal cartilage to the apex. The phonocardiographic and electrocardiographic records, taken simultaneously, show that the third heart sound appears whenever the P wave falls immediately after the T wave of the previous ventricular beat, that is, at the exact moment in which the ventricular rapid inflow phase takes place. The casual summation of the auricular systole and the ventricular inflow is the determining cause of the third heart sound.

- *Prodromal Stage of Poliomyelitis and Its Significance for Early Diagnosis and Therapy E. Wieland—p. 321
*Poliomyelitis. J. A. Toomey—p. 353
Histologic Aspects of Vasomotor Centers in Death from Diphtheria P. von Koss and B. Horányi Hechst—p. 363

Prodromal Stage of Poliomyelitis—Wieland asserts that since 1910 poliomyelitis has become more severe. Whereas before that time it attacked almost exclusively small children without prodromal signs and hardly ever was fatal, it is now observed also in older children and in adults, its lethality has increased, and meningitic, neuritic and abortive types are more frequent. However, together with the polymorphic symptomatology there appears also a formerly unknown preparalytic stage, the prodromes of poliomyelitis, which are of two types. The indefinite ones are general or localized conditions of weakness of the musculature. Walking may become faltering, jerking may appear in the arms and legs, indefinite rheumatoid pains may become manifest or the patient may suddenly collapse (like a "pocket knife") but then regain the use of his extremities. The second type of prodromal signs are definite and localized signs of neurogenic irritation and they are generally three in number: Lasègue's sign, the spine sign and rigidity of the neck. Lasègue's sign consists of a painful pressure point at the site where the sciatic nerves emerge from the pelvis, at the ischiadic foramen. The spine sign is a peculiar pain in the back and along the entire spinal cord. The third sign, the rigidity of the neck (meningism), is more noticeable than the others and consequently better known. The author emphasizes that on the early recognition and the correct estimation of the prodromal symptoms depends the early diagnosis and with this the possibility of a specific serotherapy of poliomyelitis. If the three characteristic prodromal signs are absent, which is the case in all abortive or in certain masked cases of poliomyelitis, the suspicion of poliomyelitis may be corroborated by the characteristic aspects of the cerebrospinal fluid. The author thinks that the symptomatic treatment is not made superfluous by modern serotherapy. The fact that fifteen of twenty-one patients with new poliomyelitis showed an intense redness of the pharynx and sensitive submaxillary glands, and that only five had a temporary intestinal catarrh, he considers an indication that the pharyngeal organs are the most frequent port of entry for the virus of poliomyelitis.

Poliomyelitis—Toomey agrees with some others on the point that the gastro-intestinal tract is the primary port of entry for the disease. The development of poliomyelitis may be explained, he says, by considering the virus of the disease a facultative toxin for the gray fibers. He made studies on the feces and the serum of patients with poliomyelitis. He discovered a toxic substance in the stool and the urine of patients with poliomyelitis. The spinal cord of animals that had been given injections of emulsions from the excreta of patients with poliomyelitis presented a pathologic picture similar to that in poliomyelitis. That these reactions were specific was proved by the effects of the injection of serum from patients in the acute stage and by serum from convalescents. In further experiments the author aimed at determining whether organisms of the colon or the paratyphoid groups, found in the stools of patients with poliomyelitis, have a toxic effect. He cites other factors that indicate a gastro-intestinal nature for poliomyelitis and further discusses the involvement of the sympathetic nervous system. After reviewing experiments with virus injections and attempts to produce the disease from the gastro-intestinal tract,

he describes a technic which he found effective in the experimental production of poliomyelitis by way of the gastro-intestinal tract. He points out that the anatomic conditions make it appear possible that the spread of the virus takes place along the postganglionic, sympathetic fibers that have no medulla and toward the two unprotected sites in the medulla which have no myelinated connective fibers with the sympathetic system, that is, the cervical and lumbar regions. This would explain why the terminal effects of the disease become manifest in the extremities. The author is of the opinion that the poliomyelitis virus as such is rather harmless and is not the only cause of the disease. He believes that the intestinal organisms likewise play a part in the pathogenesis of poliomyelitis.

Inhibition of Thyroid Activity by Animal Blood—Eitel and Loeser show that animal blood is capable of reducing the action of the thyroid secretion. If guinea-pigs are fed with thyroid and at the same time are given normal blood or serum, the typical decrease in weight does not become evident. Admixture of blood likewise prevents the over hasty development of tadpoles, which is ordinarily induced by the thyroid hormone. Thus it appears justified to resort to blood therapy in the treatment of disorders of the thyroid, which Bier did with success as early as 1901. Blum was able to prove that this action of the blood is not due to the protein bodies but rather to a substance that he designates as thyroid 'catechin'. The observation that the administration of blood reduces the general symptoms (loss of weight, increased metabolic rate, tachycardia, sweating, diarrhea, exophthalmos and so on), which result from an alteration in the thyroid activity, induced the author to investigate whether it influences also the site of production of the hormone, the thyroid. His assumption that this is the case was corroborated by the abolishment of the thyroid stimulating action of the thyrotropic hormone of the anterior lobe of the hypophysis following the injection of animal serum as well as following the oral administration of animal serum. The abolishment of the thyroid activating capacity of the thyrotropic hormone permits an estimation of the antithyroidal action of the market preparations that have been obtained by extraction from the blood.

Allergy and Eclampsia—Knepper was able to demonstrate in animal experiments that the combination of the serum-hyperergy experiment with injections of the hormone of the posterior lobe of the hypophysis produces changes in the organs that are typical for eclampsia. He thinks that these experiments indicate that eclampsia is a combination of the increased production of the hormone of the posterior lobe of the hypophysis with an allergic (hyperergic) reaction of the tissues.

- *Procaine Hydrochloride in Treatment of Adiposis Dolorosa (Dercum's Disease) R. Boller—p 1786
- Alcohololemia Following Intravenous Injection of Alcohol G. Dell'Acqua—p 1789

Rest Nitrogen in Blood and in Cerebrospinal Fluid—Straube and Leitritz found that the rest nitrogen in the cerebrospinal fluid reaches nearly the height of the rest nitrogen in the blood serum. The rest nitrogen quotient "serum cerebrospinal fluid" lies between 0.92 and 1.35, the mean being 1.095. This quotient increases in cases of slight increase in the rest nitrogen of the serum if the pressure of the cerebrospinal fluid

is normal, and it decreases if the lumbar pressure is increased. In nephropathies with insufficiency, the ratio between the rest nitrogen in the serum and that in the cerebrospinal fluid is the same, and it may be concluded that the same regularities exist as in other cases.

Procaine Hydrochloride in Treatment of Adiposis Dolorosa—Boller states that he first employed a procaine hydrochloride solution for the treatment of adiposis dolorosa (Dercum's disease) in 1930 and that the result was favorable. He uses a sterile 0.2 or 0.4 per cent solution of procaine hydrochloride to which a 0.4 per cent solution of sodium chloride is added. The solution should always be freshly prepared, for after several weeks it becomes yellowish and loses its efficacy. At the first injection the author administers from 10 to 20 cc., and later he gradually increases the amount to 40 or 60 cc. The injections are given daily or at intervals of several days. The author considers it advisable to make several successive injections into one part of the body and later into other parts. As a rule, after one or two injections the pains subside in the part into which the injections have been made, but they completely disappear only after several portions of the body have been treated. The author recommends the use of a needle from 10 to 12 cm. in length. The injections should be made in such a manner that hardened portions in the subcutaneous fat tissues may be reached and infiltrated. Intracutaneous injections are inadvisable. The injections are rather painful, but, since improvement is generally noticeable after two or three injections, the patients usually do not object to further injections. The author reports the histories of several cases and then reviews theories on the pathogenesis of adiposis dolorosa. He thinks that the efficacy of the procaine hydrochloride injections indicates that Dercum's disease is an obesity that is complicated by polycuritis. The procaine probably counteracts the inflammation of the nerves in the fat tissues, so that the spontaneous as well as the pressure pains disappear.

- *When Is Roentgenoscopy Necessary in Obstetrics? K. Heyrowsky—p 1630
- Tremors of Eyes in Miners M. Bartels—p 1632

Secondary Effects of Amidopyrine—Lotze studied cases of acute and chronic polyarthritis, which had been treated with amidopyrine, for the appearance of undesirable secondary manifestations. He observed five cases in which amidopyrine caused inhibition of diuresis and impairment of the excreting renal tissues. These changes proved reversible. He observed one patient, in whom a lethal amidopyrine intoxication developed with signs of general intoxication and of impairment of the central nervous system. He thinks that in this case especially predisposing factors were responsible for the unfavorable action of amidopyrine. He believes that the occasional appearance of more or less severe intoxications in the course of prolonged treatment with comparatively large doses is no reason to dispense with the use of a medicament as effective as amidopyrine in the treatment of polyarthritis.

When Is Roentgenoscopy Necessary in Obstetrics?—Heyrowsky says that roentgenoscopy should be resorted to only in those pregnant or parturient women in whom an obstetric complication is to be feared or has already developed, and in whom clinical examination does not entirely clarify the condition. He thinks that anomalies of the pelvis represent the largest number of cases in which roentgenoscopy is necessary. He admits that anomalies of the pelvis may be detected by vaginal examination, but he thinks that it is not advisable so far as the estimation of the measurements of the pelvis is to decide whether spontaneous delivery is possible or a cesarean section is necessary, and, if the latter is the case, a vaginal examination is undesirable, even if it is done under aseptic conditions. This point of view must be taken not only at the onset of the delivery but also during the last few weeks of pregnancy, for an investigation of the statistics on the mortality and the

morbidity of the cesarean operations in cases with and without vaginal examinations bears this out. Thus it is the safety of the mother that makes roentgenologic examination of the pelvis preferable to vaginal examination. The author points out that in positional anomalies of the fetal head a general surveying roentgenoscopy should be made as well as a lateral exposure. The general roentgenoscopy alone is sufficient for the determination of the position of the fetus and for the diagnosis of plural fetuses, of a monster or of the death of the fetus. The presence of several fetuses can usually be determined by palpation, but, if this is impossible, roentgenoscopy should be done. Pelvic presentation can always be detected by clinical examination, and it is unnecessary to incur the expense of a roentgenoscopy. The author rejects roentgenoscopy for the purpose of measuring the fetal head. He emphasizes that roentgenoscopy should be the last resort in obstetric diagnosis and says that it is possible to make two obstetric roentgenograms without having to fear the least damage to the fetus.

*Weltmann's Coagulation Band in Syphilis. Grete Sicher and A. Wiedmann—p. 1664

Syphilis and Tuberculosis.—Ernst made his observations on sixty-six patients who had syphilis and tuberculosis. They were detected among 6,000 patients with pulmonary tuberculosis. This number includes only those who had a positive syphilis reaction and not those who stated that they had a former syphilitic infection but now gave negative reactions. The infection with syphilis antedated the manifestation of tuberculosis in most cases by several years, the opposite occurring in only four cases. A direct unfavorable influence on the tuberculous or the syphilitic process was observed in none of the cases. The author emphasizes that the serologic examination for the presence of syphilis cannot be dispensed with in institutes for tuberculous patients, for about half of the patients state at first that they do not have the syphilitic infection. However, he thinks that the Wassermann test may be omitted and that it is sufficient to use one of the flocculation tests. The course of syphilis is usually mild in tuberculous patients. Pulmonary tuberculosis appears almost exclusively in the form of tertiary phthisis that progresses in the apicocaudal direction. As regards the life expectancy of the patients with open tuberculosis, there is no noticeable difference in patients with or without syphilis. The healing tendency is considerably less in patients with syphilis than in those without (66 per cent compared to 30 per cent). Antisyphilitic treatment often improves the therapeutic results.

Method of Short Wave Therapy.—Kowarschik points out that the short waves are used almost exclusively in the condenser or the electrical field, in which case the electrodes are separated either by an air distance or by a solid isolator such as rubber. It is suggested that the magnetic or, expressed more specifically, the electromagnetic field, be employed. The treatment in the electromagnetic field is not new as d'Arsonval introduced it under the term of autoconduction four decades ago. He suggested that the entire body, or portions of it, should be brought into wire spools (the so-called solenoids) through which high frequency currents pass. Inside of such spools there exists a magnetic field, the field lines of which run approximately parallel to the axis of the spool. This field produces induction currents in conductors placed in the spool. The author decided to take up once more the idea of d'Arsonval and to try to employ the short wave therapy in the electromagnetic field. He hoped that with a frequency 100 times as great as that which was used by d'Arsonval it would be possible to produce more convincing biologic and therapeutic actions. He describes experiments conducted in trying to devise a satisfactory instrumentarium, reports tests on the heating of stratified material plants and animals and finally describes the therapeutic application. The treatment in the spool field is not meant to be an improvement of the condenser method and does not detract from this method. Such disorders as furuncles of the face or lips disturbances of the sinuses, abscesses of the sweat glands

of the axilla and mastitis will still be treated in the condenser field. However, disorders like osteomyelitis, which involve parts of the extremities, or disorders of the different joints of the extremities, can be treated more effectively with the solenoid.

Weltmann's Coagulation Band in Syphilis.—Sicher and Wiedmann demonstrate that syphilis is one of those disorders which cause the coagulation band to deviate to the right. To explain this manifestation, they call attention to the productive character of the syphilitic process and compare it with tuberculosis. The deviation of the coagulation band to the right is entirely independent of the Wassermann reaction but it is observed more frequently in cases in which the Wassermann reaction is positive. A widening of the coagulation band (deviation to the right) is not a regular occurrence in patients with new infections, but in patients in whom the process is in the true primary stage a deviation to the right is observable. The authors emphasize that they do not wish to detract from the value of the lipid reactions or to replace them. They believe however, that by further systematic observations on the coagulation capacity of the serum they might be able to learn something new about the nature of the syphilitic process and eventually supplement the results of the lipid reactions.

*Prognosis and Treatment of Secondary Amenorrhea. E. W. Winter—p. 1694
New Method of Short Wave Treatment. J. Kowarschik—p. 1698

Prognosis and Treatment of Secondary Amenorrhea.—Winter mentions that secondary amenorrhea is that type in which up to a certain time the menstruation has been normal. He stresses the importance of a thorough general examination and discusses two cases that were treated for about two months. The result of hormone treatment was not encouraging in these cases. In the first woman the administration of more than 80,000 mouse units of estrus-inducing hormone produced a menstruation of two days' duration, but the systematic administration of estrus-inducing and corpus luteum hormone did not result in menstruation. In the second patient more than 100,000 mouse units of estrus-inducing hormone effected no menstrual bleeding, but the combination of hormones induced two regular menstruations. He thinks that in mild cases without atrophy of the uterus in which the amenorrhea has not existed a year Kaufmann's systematic treatment with estrus-inducing and corpus luteum hormones may be tried. In the more advanced cases, he advises beginning with the hormone of the anterior hypophysis and continuing with estrogenic preparations, giving daily from 300 to 400 units, partly by injection and partly by mouth. He thinks that in these cases a trial might be made with serum from pregnant women, and if, under the influence of this treatment, the function of the genitalia seems to improve (greater turgescence of uterus and vagina), the estrogenic preparations may be followed by the administration of corpus luteum. After menstruation has set in, the hormone therapy should be continued with small or medium-sized doses. The hormone treatment should be supported by general measures, by diathermy, by balneologic treatment and by providing sufficient amounts of vitamins, particularly vitamin E.

*Endocrine System in Its Relation to Chronic Rheumatism and Chronic Articular Disorders with Consideration of Therapy. H. Sauerwald—p. 1935

Surgical Prognosis in Obese and Lean Patients.—Seifert investigated the histories of patients undergoing abdominal operations. In diagrams he shows that the surgical mortality of the obese persons exceeds that of lean persons.

in operations for appendicitis, cholecystitis, ventricular ulcer and ventricular carcinoma. He analyzes the causes that lead to the fatal outcome. These diagrams show that the lean person who dies following an operation on account of an abdominal disorder generally succumbs to the disease as such or to a complication arising from the intervention (peritonitis). The death of the obese person, however, results primarily from factors determined by his obesity, the failure of the circulatory apparatus playing the most important part. The author shows further that the obese person is at a disadvantage if he survives the operation, for disturbances in the postoperative course are more frequent in obese than in lean patients. The following postoperative complications are more frequent in obese patients: suppuration of the surgical wound, bronchitis, thrombosis and infarct, pneumonia and collapse.

Relations of Endocrine System to Articular Disorders.—Sauerwald points out that a connection between the endocrine system and rheumatic and articular disorders was demonstrated by Unger more than two decades ago but that the complicated interrelations did not become sufficiently clear until Abderhalden introduced interferometry into the diagnosis of chronic articular disorders. He shows a normal curve obtained by interferometric tests on the endocrine functions, and also curves obtained on women with endocrine and articular disturbances. The latter curves indicate various endocrine disorders, but there seems to be always a predominance of the ovarian disturbance. He treated cases of rheumatic and articular diseases in women with endocrine particularly ovarian, disturbances, successfully by administration of estrus-inducing hormone. During the first eight or ten days, the patients are given daily 100 mouse units and after that every second day the same quantity. The hormone is given in the morning, on the fasting stomach. The symptoms usually become exacerbated during the first eight or ten days, but, if after that the dosage is reduced, they disappear rapidly. The short period of irritation indicates that the hormone preparation is effective. Frequently the administration of the estrus-inducing hormone improves not only the articular disturbances but also the general condition. The author considers it advisable to continue the administration of the hormone after clinical cure and to repeat it for several weeks about twice a year.

*Immediate and Late Results of Lumbar Sympathectomy in Treatment of Spontaneous Gangrene
A. N. Filatov—p. 130

Myxoglobulosis of Appendix.—According to Karavanov, the condition is characterized by distention of the lumen of the appendix by a mass consisting of granules and having the appearance of boiled sago. The pathologic picture of this condition, also known as pseudomyxoma of the appendix, is characterized by obliteration of the proximal portion of the appendix, cystlike enlargement, and a mucous colloidal content. This content is usually sterile and its chemical character is that of a pseudomucin. He reports a case and reviews forty-two cases collected from the literature. The globules found in the colloid consist of albuminous substances and of pseudomucin. Histologic studies point to a chronic inflammatory process with atrophy of the glands of the mucosa in the distal portion. The etiology of the sago-like bodies is one of retention of secreted mucus in the excretory ducts of the glands of the mucosa. The occluded ducts cause the accumulation of the mucus. Eventually the occluded duct ruptures and the rounded mass of mucus is extruded into the lumen of the appendix. The course of the disease is that of a chronic appendicitis. It has been discovered accidentally in the course of operations for some other condition than appendicitis, and at necropsies. Myxoglobulosis of the appendix is a rare form of pseudomyxoma of the appendix. The rupture of such a cystic dilatation may lead to formation of pseudomyxoma of the peritoneum.

Lumbar Sympathectomy in Treatment of Spontaneous Gangrene.—Filatov reports the results of lumbar sympathectomy in thirty-four cases of spontaneous gangrene of the lower extremities. An excellent immediate result was obtained in seventeen, a satisfactory result in eleven and no result in five; there was one death due to the infection of the operative wound and general sepsis. Of fourteen cases followed for not less than one year and as long as six years, an excellent result was obtained in nine and a satisfactory result in two. In the remaining three cases there was a return of morbid manifestations after six months, two years and three years, respectively. The author had collected 294 reported cases up to 1929 which, with his own and those of his chief, make up a total of 379 cases. A satisfactory immediate result was obtained in 80 per cent of this total. In a large proportion of the cases the result was permanent. The author considers lumbar sympathectomy a well founded procedure in cases of spontaneous gangrene of the lower extremities. Its effect is to remove the vasomotor disturbances and to improve the collateral circulation. The author stresses the importance of a faultless technic. To secure success, complete sectioning of all sympathetic fibers is necessary. The success of the procedure depends on careful selection of cases. Sympathectomy is a rational procedure in the presence of vasomotor disturbances and in the absence of diffuse thrombosis. The effect of injection of a nonspecific protein serves as a most accurate indication. The author prefers typhoid vaccine. The effects to be observed after the injection of the nonspecific protein are (1) the vasomotor index, (2) the return of pulsation or improvement in pulsation and (3) the improvement in the subjective symptoms. The vasomotor index is arrived at by comparing the rise in the local skin temperature of the involved extremity and the rise in the general body temperature. If it is more than 2 degrees, a good result may be expected.

*Intermittent Myeloblastosis. A. Nyfeldt—p. 1372

*Aleukemic Lymphatic Leukosis. O. Knudsen—p. 1374

Use of Iron in Treatment of Pernicious Anemia.—Four cases of pernicious anemia are reported in which remission after liver or stomach treatment ceased at a certain early stage and continued only after the institution of treatment with iron. Iron therapy produced a rise in both the erythrocyte count and the hemoglobin percentage. Mogensen says that this combined deficiency disease, pernicious anemia with iron deficit, is certainly more common than is usually supposed. There were no complications as a possible cause of the iron deficiency, it may be due to the demand on the iron reserves of the organism during the forced blood platelet production in the introductory remission. The possibility of a combination of pernicious anemia with simple achylic anemia is discussed.

Intermittent Myeloblastosis.—In Nyfeldt's patient, a girl aged 16, suffering from anemia, examination of the blood gave a subnormal leukocyte count with otherwise all signs of pronounced irritation of the bone marrow, and marked anemia. Treatment with liver and iron resulted in complete return to a normal blood picture, except for a slight oligochromemia. After some months, symptoms of anemia again developed and on readmission the diagnosis of myeloblastic leukemia was certain, death followed in two weeks. The author finds no analogous cases in the literature but describes a similar instance seen in experimentation with chicken myeloblastosis.

Aleukemic Lymphatic Leukosis.—Knudsen says that this case, in a girl aged 3, was interpreted as hemorrhagic leukemia (Frank) with apparent recovery (*Ugeskr. f. Læger* 96 164 [Feb. 8] 1934). Four months after discharge, the patient was readmitted. The picture gradually became more like a lymphatic leukemia and was fatal after five weeks. Necropsy confirmed the clinical diagnosis of lymphatic leukemia. Attention is called to the complete restitution between the two attacks, to the exceedingly low number of white blood corpuscles on the first admission, and to the almost complete absence of enlargement of lymph glands and spleen.

MODIFIED "COUTARD" ROENTGEN THERAPY

JAMES M MARTIN, MD

AND

CHARLES L. MARTIN, MD

DALLAS, TEXAS

Roentgen rays have been used in the treatment of malignant tumors for thirty-four years, but the general acceptance of technics delivering efficient dosages has been a very slow process. Pusey¹ reported cases of proved carcinoma of the lip treated successfully with many times an erythema dose twenty-seven years ago, but most dermatologists are still unwilling to use such effective therapy through fear of injury to normal tissues. Experienced radiologists discovered long ago that the actual cure of carcinoma requires the administration of from 5 to 10 erythema doses of x-rays, and even more in some instances. However the first well presented proof of this fact was brought forward by Martin and Quimby² in 1930, when they showed that the actual cure of adult squamous cell carcinoma requires from 7 to 10 erythema doses.

When considered in retrospect it now seems odd that the German so-called massive dose or carcinoma dose plan should have been so generally accepted when it was presented just after the World War along with other new ideas, such as increased depth doses, back scattering and shorter wavelengths. The new technic was designed to deliver from 100 to 120 per cent of an erythema dose to all parts of the malignant tumor as an effective procedure in spite of the fact that complete clinical cures had not been previously observed with such dosages. Although clinical improvement occurred, permanent results were most disappointing.

Since it had been our practice to use from 5 to 12 erythema doses as an effective treatment for squamous cell carcinoma of the skin for more than ten years, we naturally viewed the new "carcinoma dose" with some misgiving and used it in high voltage roentgen therapy with the hope that the shorter wavelengths might possess some unknown properties that would compensate for the reduced dosage. Such did not prove to be the case in our experience, and we began to cast about for a more effective technic. In 1925 Pfahler proposed his saturation method before the International Congress of Radiology in London. At that meeting he said "Very few radiologists at present

believe that every carcinoma cell can be killed by a single massive dose." He adopted the theory for the rate of decay of radiation effect in the tissues proposed by Kingery.³ So far as we have been able to ascertain, this theory was based on no actual clinical evidence. According to Pfahler's plan an erythema dose was rapidly built up in a few days and small doses were then given at short intervals the technic being so arranged that each small dose theoretically restored the level needed to produce an erythema. This plan utilized a much larger total amount of radiation than the old massive dose procedure, and it was therefore more effective. However, reference to figure 1 shows that when this technic has been carried out for a month only a little more than $2\frac{1}{2}$ erythema doses have been delivered, even when no decay is allowed for. Since most carcinomas require higher dosages than this, some more strenuous plan is desirable.

High voltage therapy is used principally in treating tumors situated beneath normal structures, and investigators have made many attempts to increase the tumor dose without materially increasing the effect on the normal tissues, in other words they have tried to increase the selective action of the rays. In America this activity has been directed for the most part toward the production of huge tubes and machines operating at higher voltages and producing much shorter wavelengths. So far the improved efficiency has not seemed to justify the large financial outlay involved. In Europe, investigators have been more interested in changes in intensity (roentgens per minute) and in the time consumed in administering radiation. Results possessing great promise have been obtained from these studies.

The experiments of Regaud and Ferroux⁴ formed the foundation for this work. It was first shown that a dose of filtered x-rays large enough to sterilize a rabbit's testicle completely would produce marked necrosis in the overlying skin when it was all given at one time. However when the dose was given in five equal fractions over a period of from thirteen to seventeen days, sterilization through destruction of the cells in the testicle still took place but the skin showed no irreparable injury. These observations indicate that the total effect on the more embryonic cells was not materially changed by the fractionization of the dose, whereas the damage in the superficial normal tissues was much less than one would be led to expect from Kingery's theoretical curves.

The possibilities accruing from the practical application of such observations are at once apparent. In 1920 Coutard⁵ began to treat patients with malignant conditions of the pharynx and larynx with huge doses divided into many fractions and administered over a period of several weeks. He used excessive filtration to reduce the intensity, but the voltage was not increased above the usual range. After making many changes he finally adopted a technic utilizing 190 kilovolts, 2 mm of zinc filter, 5 milliamperes of current, and a target skin distance of 50 cm. With these settings he found that one skin area could be given 5,000 roentgens (about 8 erythema doses) without the production of irreparable skin damage, when it was divided into ten equal parts given in ten successive days. It is true that the superficial layers of the skin were removed by this procedure but the reaction

Fig. 1—Curves illustrating the cumulative effect of fractional doses. The solid lines represent a saturation plan and the broken lines the Coutard plan. In each instance the upper curve represents the total dosage whereas the lower broken line is calculated in accordance with the theoretical curves of Kingery.

was relatively painless and healing occurred in a few weeks, the tissues being left soft and pliable and apparently not seriously damaged. When the treatment was applied to the side of the neck, the mucous membranes showed a severe reaction and formed a superficial membranous exudate, but healing was fairly rapid and no sequelae remained during long periods of observation. From his experience Coutard found that a dose of 3,500 roentgens delivered to squamous cell carcinomas of the larynx and pharynx was sufficient to produce a complete regression, which was permanent in many instances. Kingery's theory was disregarded, the tumor dose being figured without any allowance for decay of the radiation effect between treatments. The skin reactions could be reduced somewhat by giving part of the exposure from each side of the neck and calculating depth doses by the accepted methods.

5 Coutard H. Roentgen Therapy of Epitheliomas of the Tonsillar Region, Hypopharynx and Larynx from 1920 to 1926. *Am J Roentgenol* 2: 313-331 (Sept.) 1932.

Between 1920 and 1926, Coutard treated a group of 212 cases, many of which were inoperable. Despite the fact that the technic was being constantly changed and improved during this period, 20 per cent of the group remained symptom free at the end of five years. This is indeed a creditable showing.

In Germany the method is rapidly gaining favor. Kahlstorf⁶ has verified the reduction in skin effect resulting from fractionization of large doses, using rabbits as experimental animals. Schwarz⁷ attributes the increased selectivity to the low intensity and advises that it be lowered even further. Juul⁸ has shown that fractionization definitely increases the selective action of rays on animal tumor implants. Holthusen⁹ believes that fractional dosage and an increased time factor are much more important in increasing selective effects than is a reduction in wavelength. Reinsner¹⁰ has begun what should be a most valuable line of investigation in that he is studying the effects of various elapsed time intervals between treatments on the total dosage. Schroder¹¹ and Gunsett¹² report favorable results in the treatment of carcinoma of the cervix with the Coutard method. Zuppinger¹³ has used it to produce marked improvement in patients suffering from cancer of the sinuses, cheek tonsil, tongue, vocal cords, larynx and parotid, as well as resistant cases of lymphosarcoma.

The chief objection to the Coutard technic is the amount of time involved in its administration. According to the original plan, treatment was given for two hours each day and this procedure was continued for a period of several weeks. Not only is the cost of such a procedure excessive but only a few patients can be treated at one time in a clinic of average size.

In an effort to offset these objections we have arbitrarily adopted a method utilizing 200 kilovolts, a filter of 0.75 mm of copper and 1 mm of aluminum, a target-skin distance of 50 cm and a milliamperage of 6. With these settings we obtain 12 roentgens per minute (without backscattering) at the skin surface and can administer 300 roentgens in twenty-five minutes. When fourteen such doses (4,200 roentgens) are given in sixteen days (no treatments on Sundays) to one skin area, a marked reddening and desquamation with scattered areas of very superficial ulceration occurs. When sixteen doses (4,800 roentgens) are given in eighteen days, complete denudation of the skin occurs, a moist, raw looking surface being left. Areas treated usually measure not more than 15 cm on a side. With both methods, healing is complete in most instances in from three to five weeks. During the period of reaction the patient complains of some discomfort and has a little fever, but he has none of the severe pain that all experienced radiologists have learned to associate with necrotic areas produced by

very large single doses of radiation. When the treatment is given over the neck, the mucous membranes of the mouth and pharynx show a reaction of the type described by Coutard. For a week or ten days the throat is quite sore and swallowing is so difficult that it is often necessary to use a nasal tube. However the reaction in the throat usually clears up more rapidly than the skin reaction.

Our economy of time is brought about through a reduction in filter from 2 mm of zinc to 0.75 mm of copper. Contrary to the belief of many this produces only a slight change in the wavelength so long as the voltage remains the same. Whether the increase in intensity to more than twice that used by Coutard will make any material difference in the selective effect remains to be seen.

Before undertaking the calculation of efficient depth doses we felt that the amount needed to destroy a malignant tumor on the surface should be determined. For this purpose the patient shown in figure 2 was

case supplies data that will be useful in calculating the proper amounts of radiation for other types of tumors. Figure 2 shows that the normal skin in the treated area has been in no way damaged by the treatment.

The broken lines in figure 1 indicate the dosage used in this case. The upper line represents the amount of radiation effective in the tumor, according to the experiments of Regaud and Ferroux. The lower broken line is plotted in accordance with the theory of Kingery and indicates that the radiation effective in the skin at the end of thirteen days amounts to 3,200 roentgens. Since we know that such a dose would produce necrosis if given at one time, it seems quite evident that Kingery's curves do not truly represent the effect of radiation on normal skin. Curves should be worked out representing the tolerance of skin and other normal tissues for fractionated doses and no doubt this will be done in the near future. We particularly need such data for the mucosa of the intestinal tract and other internal radiosensitive structures.

Fig. 2.—A case of squamous cell carcinoma grade 3 treated by our modified Coutard technic. A total of 3,600 roentgens was delivered to one area in twelve equal doses in a period of thirteen days. The photograph on the right was made after four months. The lesion has almost healed.

selected. The growth measured almost 3 inches (7.5 cm) in diameter and was about 1 inch (2.5 cm) thick in its thickest portion. A piece of tissue was removed and diagnosed by Dr. George T. Caldwell as squamous cell carcinoma, grade 3. Since this type of malignant growth has a radiosensitivity similar to that found in tumors of the pharynx, it offered us a good chance to check Coutard's effective dosage of 3,500 roentgens.

Thirty-six hundred roentgens was divided into twelve equal parts and administered to the tumor and the surrounding skin during a period of thirteen days, one area being used. The right eye had been enucleated many years before and the deformity in this region had no connection with the malignant tumor. In a week after the cessation of therapy the skin was quite red and showed marked desquamation but no ulceration. The tumor melted away rapidly, however, leaving a granulating wound at the point of its attachment to the underlying bone. This wound has closed in slowly, so that a clean healing ulcer about three-fourths inch in diameter now marks the site of the original lesion. The patient is symptom free and the appearance indicates that the dosage was correct. This

Since we have used our modified technic for only a little more than a year, we cannot offer any statistical data of value and submit this paper only as a preliminary report. Twenty-five patients, most of them with inoperable conditions, have been treated and in practically every instance the improvement has been marked and has seemed amply to justify the temporary discomfort produced. This series includes cases of carcinoma of the cervix, ovary, breast, rectum (squamous cell type), mouth, pharynx, liver and larynx, and a radioresistant lymphosarcoma of the mediastinum. Tumors of the pharynx have shown maraculous improvement. Martin and Pfueger¹⁴ described the extreme radiosensitivity of neoplasms in this region and it constitutes therefore one of the most favorable of the internal sites for the Coutard therapy. Large breast tumors and their metastases have also responded well, and the method certainly has a definite place in the treatment of inoperable conditions.

We have on several occasions used this technic in cases of advanced carcinoma of the mouth in which

14 Martin, H. E. and Pfueger, O. H. The Comparative Radiosensitivity of Pharyngeal Tumors. *Radiology* 17: 425 (Sept.) 1931.

radium implantation had produced only partial regression. In each instance little or no added improvement was obtained, and the patients were made more uncomfortable. This outcome was of course to be expected, since there is usually little to be gained by the repetition of any radical plan of radiation therapy if the first attempt fails.

There is undoubtedly a large field of usefulness for fractionated external dosage in connection with interstitial radium implantation. In some clinics the external therapy is being administered with a large radium pack. Healy has found it most advantageous to give a preliminary series of roentgen treatments to the pelvis using a modified Coutard plan before applying radium in carcinoma of the cervix. The roentgen therapy alone causes a definite regression of the primary tumor, thereby lessening the chance of infection, and it also delivers more effective dosage to the broad ligament regions. The combined technics render radiation therapy more complicated and time consuming but the main goal is an increase in efficiency.

has been low and I believe that he has stressed this point as being advantageous on account of the more prolonged exposure which it necessitates, or permits, depending on which view one cares to take of it. This is one of the factors which the authors have altered as a matter of economy in both time and expense. Filtration also is variable, and opinion, both clinical and physical, is by no means unanimous. The authors have utilized here again the more economic filtration. In the original Coutard work and in the work of the authors the distance has remained at 50 cm. This again is a variable factor and many radiologists feel that it can be increased to advantage. The quantity of radiation in other words the number of roentgens delivered in an individual exposure alters the actual time of the individual exposure and consequently has its influence on the total period to be consumed in the full round of treatment. By adjustment of these factors and variations of the total quantity of radiation being used the total treatment interval may be adjusted anywhere from a fortnight to six weeks. For several years I have employed a set of factors very close to those of the authors, except with filtration which has been slightly heavier (0.87 mm. of copper plus a secondary aluminum filter). I have checked over a number of these cases and find that our total quantities of radiation agree surprisingly well. This principle of multiple

Fig. 3—Squamous cell carcinoma grade 3 of the pharynx and larynx which was producing dysphagia and marked dyspnea. The drawing on the right was made three months after the completion of the modified Coutard technic when the patient was entirely symptom free.

SUMMARY

1 The technic of high voltage roentgen therapy has progressed from the single massive dose through the saturation method to the more modern Coutard plan.

2 Coutard has definitely increased the selective action of x-rays on malignant tissue by reducing the intensity with excessive filtration and prolonging the time by the fractionization of very large doses.

3 A modification of the Coutard technic here described is apparently efficient and much less time consuming than the French procedure.

Baylor University Hospital

ABSTRACT OF DISCUSSION

DR. DOUGLAS QUICK, New York: The Coutard technic is really the statement of a principle rather than the enunciation of a definite and rigid technic. The principle involved is that of multiple exposure for the most part daily with 200 kilovolts equipment approximately, which over a period of from three to five or six weeks in certain instances produces a membranous reaction on the mucous membrane of the mouth or throat and secondarily a superficial destruction of skin. There are various factors any one of which may be varied. Voltage is reasonably standard around 200 kilovolts but need not necessarily remain so. The milliamperage as employed by Dr. Coutard

divided doses has brought about more general interest in roentgen therapy than anything since 200 kilovolt radiation was ushered in a few years ago by the German "massive dose" technic. So many factors are variable that a study of the variations possible, from the clinical standpoint, is fascinating. Clinically, radiologists are governed in doing this by close observation of the reactions, and guided to a degree by their associates from the laboratory, not forgetting that beyond a certain point clinical reactions and physical laboratory calculations may possibly become divergent.

DR. E. L. RAPINS, Iowa City: Since syphilis is a common complication in malignant growths of the neck and pharynx I wonder whether the authors noticed if the skin of people with syphilis and carcinoma was more sensitive to irradiation, provided they were getting intensive antisyphilitic treatment at the same time.

DR. G. E. PFAHLER, Philadelphia: The authors referred to the saturation method of treatment. I want to call attention to the fact that neither Kingery, Pfahler nor Coutard originated the principles underlying the technic described. It involves practical dosage carried over long periods of time and Dr. Coutard has very wisely added higher filtration. He has taught that in certain localities particularly the neck and face, or wherever there is abundance of good circulation irradiation can be carried to a much severer degree or higher dosage than was formerly thought possible. One who attempts, however, to carry that dosage to the same degree over the abdomen will regret it. I have talked this over with Dr. Coutard and he agrees that

in principle there is no difference whatever between the saturation method and the Coutard method. I would like to correct the authors on one point: if they carry this method out properly, they will do as I am doing, give from six to eight erythema doses in four weeks. That is exactly what Dr. Coutard is giving. Dr. Reisner, working in the Hopfelfelder Laboratories in Frankfurt, has shown that the saturation curves which I drew are too high, that the dosage is too low, and I agree with him. I have increased that dosage along these saturation curves. As a safe procedure I have increased the dosage 20 per cent at each point. I think it probably can be increased more. The advantage of these so-called saturation methods is that if one does what the authors have done, instead of treating the patient twice a day as I recommended in 1925 one finds it necessary to treat them once a day, or if because of illness or some other interruption the patient cannot get there for two, three or four days, the saturation curve will enable one to bring the dosage up and give the required dosage. With regard to the higher filtration or wavelengths, if I could handle the thousand kilovolt apparatus with the facility that I can handle the 200 today, I would unquestionably use a million volts and higher filtration, but the difficulty which I see in that technique is that it is too cumbersome and one sacrifices in the ability to direct the rays carefully what one gains in other respects. That will be overcome in the future. All that is needed is to apply one's energies as has been done with the 200 kilovolt dose, the technique of which is just being learned. Physicians should not allow themselves to be carried away too much by these physical experiments. Clinical observations have taught them more in medicine than anything else.

DR. MAURICE LENZ, New York. When five years ago I started treating carcinomas of the pharynx and larynx and other malignant growths with the Coutard method modified as regards time of treatment, I felt as enthusiastic as the authors do today. I am still as enthusiastic as they are about administering 25 roentgens, 10 roentgens or, as the Memorial does 65 roentgens per minute, provided the field used is small: it is not larger than 7 by 7 or 8 by 8 cm. However when the same technique is tried in larger fields (20 by 20 or 15 by 20 cm) difficulties are apt to arise. In such fields when I gave 25 roentgens per minute, with the proviso that the total dosage was up to 3,000 roentgens, complications arose, whereas I was able to give this dosage when the field was less than 10 by 10 cm. I believe the crux of the situation is size of field when the dosage is as large as Coutard uses. If the daily administration of roentgens ranges somewhere between 300 and 400 roentgens, fields as large as 15 by 20 cannot be used if 65 roentgens or 25 roentgens per minute is to be given. For such fields there is no short cut. One has to stick, I believe to either what Coutard says or might go up to 10 roentgens per minute.

DR. A. G. RAY, Jackson, Ohio. It is the end results that tell more than anything. I have a 65,000 volt machine—very low voltage, I will admit, but the results are good. I use 3 milliamperes and give an exposure of ten minutes until the patients get the erythema, then I put it down to 2 or 15 milliamperes and always give an exposure of ten minutes. I give exposures five days apart and give eight exposures. I have treated more than a hundred epitheliomas and carcinomas. One carcinoma of the bone was arrested and the patient lived four years. In a sarcoma of the breast the ulcer was about 3 inches wide. I exposed that fourteen times at intervals of five days taking off the dead tissue every time the patient came in until the gland was removed. The cure lasted eight years when it recurred in the lung. I have given the exposures empirically. I think from the results of sixteen years' experience with three x-ray burns, I obtained a basis and I have been acting on that basis ever since. I have never failed to cure an epithelioma.

DR. I. S. TROSTLER, Chicago. I have a method by which one can protect oneself from lawsuits. A statement releasing the radiologist an ordinary release given before the treatment, has no force at all, but if one has the patient sign a statement worded as follows, "Recognizing that I have a disease which will destroy my life, I hereby give consent to the use of unusual and extraordinary methods in the treatment of my case, one will be protected."

DR. J. M. MARTIN, Dallas, Texas. The discussion brought out some very helpful points. While we are enthusiastic about the Coutard method and are fairly well satisfied with the modified technique adopted, we are aware that there are other modifications of this method that will produce equally good results. In referring to Dr. Pfahler's saturation technique I was quoting from his London paper. I am glad to hear him say that his total dose in roentgens has been materially increased. Replying to Dr. Trostler. While the dermatitis is considerable in all these cases we have had no legal complications. Usually a surgeon, a dermatologist and a pathologist see these cases with us. Most of the patients so treated have advanced carcinoma with one foot in the grave. We go into details in telling them just what to expect and how long they will be in recovering from the effects of the treatment. After recovery the gratitude of these people is unbounded. These cases should always be kept under observation and control. Ultraviolet ray treatment for the dermatitis is harmful. Likewise sunburn over the areas treated will aggravate the dermatitis. I want to thank Dr. Quick for his liberal discussion of my paper. If there is a better modification of the Coutard method of treatment, we will be glad to learn about it. The radiologist is the only hope for these unfortunate cancer victims.

THE ROENTGEN DIAGNOSIS AND TREATMENT OF TUMORS OF THE BLADDER

THEIR SERIAL STUDY WITH PNEUMOCYSTOGRAMS,
SHOWING RESULTS OF TREATMENT
BY IRRADIATION

GEORGE E. PFAHLER, M.D., Sc.D.
AND
JACOB H. VASTINE, M.D.
PHILADELPHIA

So far as we have been able to find, pneumocystography was first used in the diagnosis of tumors of the bladder by one of us (Pfahler) in 1908, and this method was discussed by him at various roentgenology meetings from time to time. A formal presentation was made together with a lantern slide demonstration of a number of tumors of the bladder before the Philadelphia Roentgen Society on May 8, 1919.¹ However, Braasch says "Air was used in the bladder for the demonstration of a diverticulum by Kellar in 1904" (reference not given).

This method of study of tumors of the bladder we believe should be used as a routine because of the valuable primary and supplementary information that is obtained. We believe that pneumocystography cannot replace cystoscopy, but in the management of a serious condition such as tumors in the bladder, nothing that would be helpful should be neglected. Pneumocystography is harmless and painless and requires no great amount of paraphernalia. Therefore it can be used in conjunction with cystoscopy or, at times, when cystoscopy cannot be performed. In many cases the examination by a cystoscopist is not practical for one of the following reasons:

- 1 Because of the fear of pain that generally accompanies cystoscopic examinations
- 2 Because of the inability to pass the cystoscope
- 3 Because of severe hemorrhage, which clouds the field of vision in the bladder
- 4 Because an expert cystoscopist is not always available

Read before the Section on Radiology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.
¹ Pfahler, G. E. The Injection of Air for the Roentgen Diagnosis of Tumors of the Bladder. *Am. J. Roentgenol.* 6: 371-375 (Aug.) 1919.

5 Because of possible objections on the part of patients, which leads them to postpone or refuse a cystoscopic examination and thus delay the diagnosis

TECHNIC FOR PNEUMOCYSTOGRAM

It is our custom to make a general film of the entire urinary tract posteriorly and one smaller film anteriorly of the bladder preceding the injection of air. These preliminary films will demonstrate any opaque calculus but they are particularly useful in demonstrating any

Fig 1 (case 1)—A T J T a man aged 49 referred March 21 1925 by Dr F J Dever on account of carcinoma of the glans penis which had existed for one year. Treated successfully by radium x-rays and electrocoagulation. A three years later June 8 1928 the patient returned with a history of hematuria for six months. The pneumocystogram shows an ulcerating broad based tumor of irregular density occupying the left wall of the bladder and extending over toward the region of the left ureter. It projected into the bladder 5 cm and the base was 3 cm. A second tumor on the posterior wall of the bladder was approximately 2 cm in diameter. B after treatment by high voltage roentgen therapy and also by cystoscopic electrocoagulation done by Dr Wilbur Haines. A pneumocystogram made May 8 1929 shows tumors entirely gone. The bladder is normal throughout. The patient was still well April 17 1934 five years after treatment.

localized collection of gas in the rectum or pelvic colon which might otherwise be confusing in the interpretation of subsequent pneumocystograms.

The urethral orifice is cleansed with an antiseptic solution. A sterile rubber catheter of the largest size that will pass easily is then lubricated and is introduced in the usual manner. Any retained urine is withdrawn and a special effort should be made to extract all the urine for if any fluid remains in the bladder it tends to obscure the presence of a tumor. If there is an obstruction from a prominent middle lobe of the prostate, it may be necessary to use a prostatic catheter. After this catheter is introduced, it is connected by means of glass tubing to an atomizer bulb. If one uses for this purpose glass tubing that is wide at one end it is possible to introduce cotton so as to filter the air as it is injected. We believe that there is little danger of infection from any air injected, because it is not likely that the soil will be suitable for the development of any germs from the air.

After the urine has been withdrawn and the atomizer bulb firmly attached air is injected by gentle compression of the thumb and index finger. The air is pumped into the bladder until the patient complains of bladder

distention or until distention of the bladder can be felt by palpation, or an outline is made by percussion. A pair of hemostatic forceps is then clamped on the catheter, and this is strapped firmly with the adhesive plaster to the surface of the thigh. To economize on time, all these preparations should be made in advance and the patient should be lying on the Potter-Bucky diaphragm with the tube set in position, so that there will be no unnecessary delay or discomfort.

EXPOSURES

We usually make one or two films posteriorly first and then rotate the patient on to the abdomen, being especially cautious that the catheter is not disturbed in turning the patient on to the abdomen, then at least two additional films are made anteriorly. Most tumors are shown best in the anterior position, because most tumors occupy the posterior wall and therefore when the patient is lying on the abdomen, the air surrounds the tumor. It is at times helpful also to make oblique anterior films. Especially is this valuable when diverticula are associated. If one chooses to demonstrate more definitely the presence of diverticula, it would probably be best to release the air by releasing the clamp and inject the bladder with an opaque solution, such as 12.5 per cent sodium bromide. We have not found the opaque cystograms of additional value in the diagnosis of tumors, but the opaque cystograms are especially valuable in the diagnosis of diverticula.

OBJECTIONS TO THE EXAMINATION

After making several hundred of these examinations, we can state definitely that no harm has ever resulted, and there is practically no more inconvenience to the patient than that which would follow an ordinary catheterization. We have never had any case of air embolus follow one of these injections and there has never been any emphysema in the tissues. Bedrna

Fig 2 (case 2)—Mrs G W S aged 55 was referred by Dr J M Anders June 13 1930 on account of hematuria for several months. A tumor irregular in outline with a broad infiltrating base surrounding the urethra, about the size of a hen's egg. The patient was given high voltage roentgen treatment. B after three months on Sept 10 1930 reexamination showed that five sixths of the tumor had disappeared. All the patient's symptoms had gone. C after six months on Jan 16 1931 the patient was reexamined and all the tumor had disappeared. On July 28 1932 examination showed that the bladder was entirely well. The patient is without any symptoms four years after treatment.

and Simon have reported on 345 cases in which air was injected directly into the ureter and kidney pelvis with no complications. There certainly would be more risk from injection of air directly into the pelvis of the kidney than from injection into the bladder. The patient is always conscious and as soon as the patient complains of a sensation of fullness the injection is stopped. We believe, therefore, that no harm is likely to occur. Any external pressure effect from fecal matter in the rectum can easily be eliminated by pre-

liminary evacuation of the rectum, and the presence of any such matter can easily be determined by a preliminary digital examination by rectum

INTERPRETATION

We have succeeded in demonstrating both benign and malignant tumors varying in size from 1 to 8 cm. It is not always possible, of course to make a pathologic diagnosis by means of pneumocystography as to malignancy or benignity just as it is not always possible to make a diagnosis cystoscopically or macroscopically. In general, however, if a tumor is small sharply defined and pedunculated and especially if there are multiple tumors, the probabilities are that it is benign. If it is large, irregular on the surface and associated with a broad base it is probably malignant. If the tumor has definitely infiltrated the bladder wall so that it cannot stretch normally one obtains more definite evidence of a malignant growth than could be obtained cystoscopically.

Since urologists state definitely that all tumors of the bladder are potentially malignant, the important matter is to demonstrate the tumor and to get rid of it by the best means possible, according to the indications in any individual case.

TREATMENT OF TUMORS OF THE BLADDER

Through the kind cooperation of the surgeons and urologists with whom we have been associated, we have been privileged to make various combinations in the treatment of bladder tumors, such as (1) excision preceded or followed by irradiation, (2) cystotomy and direct surface application of radium, (3) cystotomy, electrocoagulation and insertion of radium

Relative Results Obtained by Various Methods*

Treatment	No of Patients	Treated Prior to 3 Years Ago				
		Alive	Dead	Well	Survival	Not Traced

* Our previous publications gave a more complete discussion of the various methods of treatment other than high voltage roentgen therapy supplemented by cystoscopic electrocoagulation.

needles or seeds, (4) cystotomy, electrocoagulation, and surface application of radium to the base of the tumor, (5) preliminary roentgen therapy, local destruction, subsequently followed by additional roentgen therapy, and (6) high voltage roentgen therapy, with high filtration, supplemented, if necessary, with electrocoagulation (through the cystoscope) of any remnant that does not respond to irradiation. Our most brilliant results, which have been the most pleasing to the patients have been obtained by the last two methods.

Recently in the discussion of this subject before the Pan-American Medical Congress, Dr. Hugh Young

stated that at least three fourths of the tumors of the bladder are inoperable, chiefly because approximately 75 per cent occupy the region of the ureters or the urethral orifice, and since all tumors of the bladder are potentially malignant it would seem that one must aim at early diagnosis, and early and thorough treatment by a combination of irradiation and perhaps, electrocoagulation. Small benign tumors are being destroyed daily by urologists by cystoscopic electrocoagulation but it is also well known that these tumors

Fig. 3 (case 3).—A man aged 54, was referred May 6 1933 by Dr. William Mackinney on account of hematuria for only two days. By cystoscope and by pneumocystogram A there was found an ulcerating infiltrating carcinoma involving 6 cm. of the upper left quadrant of the bladder and located more anteriorly than posteriorly. It projected into the bladder 3 cm. B a pneumocystogram made Sept. 11 1933 four months after high voltage roentgen therapy was begun shows that most of the infiltrating of the bladder wall was gone the density of the tumor has decreased, and the size of the tumor has decreased about 50 per cent. The patient was treated only with high voltage roentgen therapy 200 kilovolts filtered through 2 mm. of copper the treatment being given through five different portals of entry directed toward the tumor area. C Jan. 8 1934 a remnant of the tumor which was finally destroyed by Dr. Mackinney with electrocoagulation. The patient was treated during a period of about six months receiving a total of approximately 3500 roentgens through each portal of entry. During all this time the patient continued his occupation as a practicing physician. D May 24 1934 the bladder wall was smooth in outline the patient was symptomatically well cystoscopically well and well as shown by the pneumocystogram. Note the complete distention of the bladder and the perfectly smooth walls. If such results can be obtained it will be a great inducement for patients to seek treatment early.

commonly recur after such treatment, therefore it has seemed to Dr. Bothe and ourselves that it would be advisable to give preliminary irradiation, then destroy the tumors and follow it with an additional moderate amount of irradiation (fig. 4).

In dealing with large and definitely malignant tumors, no rule can be established, but a general plan of treatment should be laid out at the very beginning. Such a plan can probably be best and most practically made if there is a conference with the family physician, the urologist and the radiologist, for all three of these physicians need to cooperate in order to obtain the best results for the greatest number of cures.

We believe that when dealing with an inoperable case it is advisable to begin the treatment with the thought of overcoming the disease completely by irradiation, for if one succeeds with such treatment the

results are ideal. The bladder walls are restored to normal, the patient is scarcely interrupted from work, and bladder functions are normal. In order to carry out such radiologic treatment it is necessary to use high voltage roentgen therapy and we have used 200 kilovolts constant potential, with 2 mm of copper filtration, usually at a distance of 50 cm, making use either of 2 or 4 milliamperes of current, so as to prolong the irradiation effect. The patient is treated daily, or preferably twice a day usually with about 200 roentgens. The amount of the dose will depend somewhat on the reaction of the patient to treatment. We aim to deliver from 3000 to 5000 roentgens into the tumor area. The pneumocystogram is especially useful in outlining and locating the extent of the growth. This then permits the radiologist to direct his beam of rays toward this disease and then there should be as much cross-firing as is practical, but one must be most cautious as to the dosage in the subcutaneous tissue. The subcutaneous tissue of the abdominal wall is not well supplied with blood vessels therefore heavy irradiation is more likely to be followed by fibrosis or necrosis.

In giving this radiation it is our aim to deliver into the tumor tissue a full erythema dose as rapidly as is consistent with the patient's general condition. This

As a result of irradiation, one commonly succeeds in arresting the hematuria, sometimes within a few days, generally within a few weeks. In the more sensitive group of tumors, one may expect the entire tumor to disappear (fig 2). By means of the pneumocystogram one is enabled to measure photographically the progressive reduction in the size of the tumor and, finally, to note its complete disappearance. It is also possible subsequently by means of the pneumocystogram to determine the absence of any tumor tissue in the bladder. The absence of a tumor in the bladder can be determined only if the work is thoroughly and skillfully done. In this work it is never economy to attempt to save on the use of films for it is not infrequent to find a tumor not showing at all in one position and yet showing very clearly in another position.

CONCLUSION

Tumors of the bladder varying from 1 cm. to a large size can be demonstrated clearly by means of pneumocystograms.

The progressive enlargement or the progressive reduction can be shown and recorded photographically.

The method of examination is comparatively painless and harmless.

Fig 4 (case 4)—A woman aged 43 referred by Dr Albert Bothe on Oct. 26 1933 had hematuria six weeks following a fall with no pain. A cystoscopic examination and pneumocystograms show a sharply defined tumor approximately 2 cm in diameter located about 5 cm. to the left of the prethral orifice. This tumor has associated with it the shadow of a second smaller tumor which has double the density but which is still sharply defined. A second papilloma is located at the left border of the sphincter and approximately 0.5 cm in diameter. A third papilloma is located about 8 cm to the left of the sphincter. All these lesions have the appearance of being benign as determined both by cystoscope and by pneumocystogram. B Dec. 4 1933 these lesions were reduced in density and reduced in size approximately 50 per cent. The third lesion at the left wall of the bladder is entirely gone. Following this pneumocystogram Dr Bothe destroyed the remainder of the tumor cystoscopically. C May 7 1934 the tumors were entirely gone and the bladder wall was smooth and healthy. The depression in the upper right border is due to the distended cecum.

usually requires from four days to a week. It is our aim then to keep the irradiation value in this tumor tissue up to the saturation value of an erythema dose, during a period of an additional three or four weeks. This requires a tremendous amount of treatment if it is carefully done. Under these circumstances the tumor may disappear completely (fig 2), or the tumor may be reduced in size (fig 3) and become more or less stationary. It may then be necessary to destroy the remainder by electrocoagulation cystoscopically, as has been done in association with William Mackinney. In giving these treatments it is not only advisable always to measure the saturation value in each portal of entry and the saturation value in the tumor tissue, but one must take account of the total value of irradiation given through any portal. When treatment is given through the abdominal fat some risk is involved when one exceeds a total of 300 per cent of an erythema dose. In certain parts of the body where the circulation in the subcutaneous tissue is good it would be possible to give a total of 600 per cent of an erythema dose in divided doses.

Under treatment by high voltage roentgen therapy one can record from time to time serially the progressive disappearance of the tumor.

1930 Chestnut Street

ABSTRACT OF DISCUSSION

DR. RUSSELL S. FERGUSON, New York. The pneumocystogram that the authors have described and stated the value of in following the regression of tumors in the bladder is used more widely by the urologist than the authors suspect apparently. In 159 of 902 cases in the Bladder Tumor Registry, pneumocystograms were made. The procedure was said to be of value in the diagnosis of bladder carcinoma in 108 of these. The thing that the urologist does not appreciate however, is the value of the x-rays in the treatment of bladder carcinoma. The x-rays were first used in this country by Gray in Richmond Va. in 1906. He had the bladder opened and treated the tumor through a cone inserted into the bladder. That method of course under the conditions existing at that time fell into immediate disrepute. The method has been revived recently by Rose in St. Louis who has devised a stabilizing tractor for the bladder and then treats it with low voltage x-rays 85 kilovolts without any filtration whatever and delivers

doses up to 2,000 roentgens at one sitting. This is most interesting. I want Rose's results with curiosity. A more favored technic and one that I feel deserves development at the hands of the urologist, is the divided dose technic in bladder carcinoma. I think that some definite policy must be adopted in the management of these cases. Bladder carcinoma on the average will not yield to a tissue dose of less than 8 or 10 erythemias. This is shown by the work of Dean and Qumby, who measured the tissue doses delivered in the treatment of a series of bladder tumors. If any such dose is to be delivered by external means of irradiation, it must be delivered by the divided dose technic. That can be done and has been done successfully in the institution in which I work within the last eighteen months by Dean. The best results, however, seem to be obtained when it is known in advance that the tumor is either a grade 3 or a grade 4 bladder carcinoma. Grade 1 and grade 2 carcinomas especially those showing squamous pearls are radioresistant and will not yield to the average dose that can be gotten into the bladder in this manner. I would therefore suggest to the radiologist that he urge the urologist to look more carefully into the possibilities of roentgen treatment of carcinoma of the bladder, adopt a policy of biopsy in every instance, utilize the Coutard technic or some modification of it in delivering tissue doses adequate to grades 3 and 4 bladder carcinomas, and avoid treatment of grades 1 and 2 tumors by that technic.

DR. B. S. BARRINGER, New York. Radiologists have used for many years the technic described by the authors. Stereoscopic pictures have been found to tell more than simple cystograms. I am inclined to think, from a urologic standpoint, that I can gain a better idea of the tumor from the pathologic examination and from an attempted grading of it than from the cystograms. I confess that in a certain number of cases I have been confused by the pictures and radiologists are not all as expert in reading the cystogram as are Drs. Pfahler and Vastine. I want to emphasize what Dr. Ferguson said about the treatment in the future by external irradiation of bladder tumors. Up to about a year ago there were two methods of treatment. I am now speaking of carcinoma not papilloma. They were the only two methods that offered anything: one was removal by surgery and the other was radium applied suprapubically or through the cystoscope. I am biased. I have used radium. One can go further with radium than by operation. Tumors can be attacked that are quite inoperable with some chance of success by radium implants. However, there are certain tumors in the highest grade of malignancy, grade 4—fortunately they are rarely seen—that are not attacked by either operation or radium successfully. I have only one grade 4 tumor well eight years. Those tumors should be irradiated externally before anything is done after the specimen and the cystogram have been examined and then if that does not do the external radiation should be reinforced by some other form of internal radiation. Whether that is applicable to grade 3 tumors or not I don't know. I think that extensive grade 3 tumors difficult to remove or irradiate should be attacked by preliminary external irradiation. That is the next move for the future and I think that probably 5 per cent should be added to five-year cures with the careful application of external irradiation.

DR. LEO DOLAN, Toledo, Ohio. In regard to advocating widespread usage of pneumocystograms, I would like to add a word of warning regarding the amount of air pressure used in the bladder. There exists the possibility of air embolism when considerable unmeasured pressure is used. The safer method of cystoscopy should be preferred to the possible dangers encountered in widespread uncontrolled pneumocystography.

DR. GEORGE E. PFAHLER, Philadelphia. One of the advantages of the pneumocystogram and of roentgen therapy is this. Urologists say that from 65 to 75 per cent of the carcinomas of the bladder are inoperable. Therefore radiologists certainly have plenty of material on which they should work and lives that they should try to save. Here is a method that can be used. The pneumocystogram may be of no particular value to the urologist. There is no thought of replacing cystoscopy but if one has a picture of where that tumor is located and

its size and degree of infiltration and can follow its progression one can give more careful treatment and can direct the radiation better than one can by any description from the urologist. With regard to air embolism, I should like to know whether any one has produced an air embolism by this process. I haven't in approximately twenty-six years. Furthermore, I know that it is an accepted method of diagnosis to distend the pelvis of the kidney with air, as is done in the Schmieden clinic and in a number of others, and if there is no danger in distending the pelvis of the kidney with air or oxygen, certainly there is no danger in distending the bladder when the patient is conscious at all times and says "Doctor, that is hurting me."

CHANGES IN THE GASTRO-INTESTINAL TRACT IN DEFICIENCY STATES

WITH SPECIAL REFERENCE TO THE SMALL INTESTINE. A ROENTGENOLOGIC AND CLINICAL STUDY OF FORTY CASES

THOMAS T. MACKIE, M.D.

AND

ROBERT E. POUND, M.D.

NEW YORK

Deficiency disease may result from a defective dietary or from abnormal physiology of the gastro-intestinal tract. Defective absorption constitutes one of the outstanding features of sprue and in certain cases has been shown to condition the development of the deficiency factors of the disease.¹ This occurs without extensive pathologic changes in the structure of the small intestine apart from atrophy that is not disproportionate to the general wasting of the body and the viscera.² We have observed advanced deficiency disease in several severe cases of ulcerative colitis. This suggested the possibility of a similar mechanism and led to the detailed clinical and radiologic investigation of a large group of cases of chronic ulcerative colitis.

Evidence of deficiency states was found in 63 per cent of seventy-five cases studied. These conditions have presented the characteristics of partial deprivation of certain vitamins, of protein, and of important inorganic elements. The diagnostic criteria have been limited to the objective changes that have been shown to occur in deficiency diseases. The buccal and lingual mucous membranes have presented abnormalities analogous to those encountered in sprue, pellagra and pernicious anemia. The skin has shown changes similar to those reported in vitamin A deficiency³ and in pellagra. Nutritional edema has occurred in advanced cases without evidence of cardiac or renal insufficiency. Certain of the patients have presented abnormalities of the inorganic constituents of the blood, notably reduction of blood calcium and disturbance of the acid-base mechanism. One case showed peripheral neuritis similar to that occurring in beriberi.

The frequent occurrence of these deficiency states has led us to believe that they may play an important part in the pathology of chronic ulcerative colitis. They have been most numerous and most severe in advanced and serious cases of the disease, and less evident or

entirely lacking in the milder forms. It has seldom been possible to elicit a history of defective dietary. Consideration of possible etiologic factors suggested among others, too rapid passage of the food constituents through the intestinal tract or abnormalities of the small intestine producing defective absorption of the products of digestion.

Three cases of sprue and thirty-seven cases of chronic ulcerative colitis have been studied radiographically to

Fig. 1—Irregular size and shape of lumen and irregularities of mucosal pattern in a case of sprue. Barium collected in numerous irregularly spaced segments.

gather evidence on these points. The latter represent a wide variety of clinical and pathologic types. Nine patients who were seriously ill were hospitalized, the remainder were ambulatory. The colon lesions varied from the mild forms of localized proctitis to the advanced stage of extensive involvement of the entire length of this segment. The cases have been classified on the basis of the clinical observations. Clinical stage 1 includes all cases showing no evidence of deficiency disease, ten patients fall within this group. Clinical stage 2 comprises those presenting mild to moderate grades of such states, twenty-one cases are listed in this group. Clinical stage 3 is characterized by advanced deficiency states, six of the patients are included within this group.

Bacteriologic and serologic studies demonstrated infection by various strains of *B. dysenteriae* in nine of the thirty-seven cases of ulcerative colitis. Six others agglutinated stock strains of these organisms to diagnostic titer. The remaining patients fall within the classification of so-called nonspecific or idiopathic chronic ulcerative colitis.

The technic of the radiologic examination of the small intestine is as follows. A barium meal, four heaping tablespoonfuls of barium sulphate suspended in three fourths of an iced tea glass of water, is given to the patient about 9 o'clock in the morning, on a fasting stomach. In some of the first cases dextrose solution was used instead of water to determine whether or not

food value in the meal was necessary. This did not alter the conditions found.

Following the ingestion of barium sulphate, a 14 by 17 inch film is made of the abdomen in the posterior anterior direction with the patient prone, at intervals of five minutes, thirty minutes and one, two, four, six and twenty-four hours. These intervals are subject to variation. Each film is developed immediately after exposure, and as the changes appear the intervals may be varied to suit the individual case. We believe these to be the minimum number of examinations needed. After the six hour film or its equivalent the patient resumes his normal diet and no further fasting is required.

The voltage and milliamperage used should be adequate to secure clear sharp detail with a maximum exposure time of one-fourth second. One-tenth second is preferable. These short exposures reduce the possibility of motion. The Bucky diaphragm is not necessary and motion is more apt to occur when it is used.

The two main changes encountered in the small intestine are variation in the contour and size of the lumen, and alteration of the normal motor phenomena. They vary with the severity of the process. In the third or severe clinical stage the characteristic changes are invariably present and easily recognized. In the first and second stages the changes are usually present but of lesser intensity, and occasionally no abnormalities are found.

Fig. 2—Duodenal changes: dilatation; enlargement of the circular markings; collection of gas; upper jejunal coils filled showing some widening of the mucosal markings.

The duodenum shows a thickening or widening of the circular markings in almost all severe cases and in certain of the moderately severe ones. The lumen is frequently dilated and contains gas. The appearance resembles duodenitis except that no contracture or spasm has been noted in any of the cases in this series.

In the jejunum the valvulae conniventes are thickened and the spacings between them widened. The normal mucosal pattern is distorted by the irregularities in the size of the valvulae conniventes. In the partially

filled segments it is often bizarre in appearance. The lumen is frequently dilated and this dilatation may be confined to local groups of coils or isolated coils.

The barium usually passes very slowly through the jejunum and is apt to move by groups of coils. It tends to collect in a short segment while the segments proximal and distal are empty. The filled portion is dilated and smooth in appearance, and no peristaltic action is visible. All of the barium that has passed

Fig 3—Collection of barium in isolated coils. Segments proximal and distal to the filled segments contain little if any barium referred to as pocketing.

into the small intestine may be collected in a small group of coils. The intestine proximal and distal to the filled area is empty. At the subsequent examination the distribution is similar but the filled group lies at a lower level. There is no intestinal gas in the groups proximal or distal to the filled groups. When this so-called group movement is present, the stomach empties spasmodically. The flow into the duodenum is interrupted, apparently to correspond to the local delay in the forward progress of the barium.

The changes in the ileum are quite similar to those noted in the jejunum. The grouping of the coils may be abnormal, and isolated coils frequently assume a sausage shape. When a group of these dilated coils is filled with barium, the appearance is suggestive of a cluster of bologna. The barium frequently will collect in a very short dilated segment presenting an appearance resembling a large diverticulum. The coils adjacent to this "localized pocketing" are empty. The lower ileum seems to be the site of most frequent and early involvement. Occasionally the barium passes rapidly through the terminal portion, but this is the exception rather than the rule. The course of the coils in this area is often straighter than normal suggesting a lack of pliability. No definite ulceration has been demonstrated in any of our cases roentgenographically. No contractures have been present.

The outstanding feature of the rate of progress of the barium meal through the small intestine is that the

rapidity is not increased over the normal. The rate of passage is subject to wide variation and does not necessarily conform to the clinical stage of the disease. The shortest emptying time was four hours. In five cases the small intestine was empty at the time of the last examination. In four cases more than six hours was required for the head of the barium column to reach the cecum. Twenty-four of the cases of ulcerative colitis and the three cases of sprue showed a definite twenty-four hour barium residue in the colon. This was distributed predominantly in the right half and occurred despite coexistent and active diarrhea. The barium enema in cases presenting the small intestine changes has shown no constant relationship between these abnormalities and the extent and the severity of the lesions in the colon. In numerous instances changes in the small intestine have been associated with a normal cecum and proximal colon. It is evident therefore that they are not the result of extension by continuity of the inflammatory process in the wall of the colon.

We have encountered identical changes varying only in degree, in the small intestine in three cases of sprue. One of these has been reported previously.⁴ Snell and Camp⁵ have recently noted similar phenomena in four cases of idiopathic steatorrhea or sprue.

These abnormalities in the small intestine we interpret to indicate varying degrees of edema of the mucosa, derangement of normal motor function and abnormal variations in tone of the intestinal musculature. They

Fig 4—Pocketing in ileum. All barium collected in a short segment in midline; no barium proximal or distal to filled segment; cessation of gastric peristalsis.

vary in intensity and in extent in the individual case from time to time. In several instances reexamination after the lapse of a few weeks has shown marked improvement, and in others an increase in the severity of the process.

The actual pathologic condition underlying the roentgenologic changes is not definite. To correlate the

phenomena visualized by x-rays with the structural changes occurring in the intestinal wall necessitates the study of biopsy specimens. The rapidity of post-mortem change renders autopsy material an uncertain criterion of living pathologic changes in these tissues. Tissue for examination has been obtained from only four of the cases studied. In three of these a section of terminal ileum was removed surgically. However, one of these patients had a previously performed ileo-

venously have been shown to exert a characteristic action on the intestinal tract of experimental animals. They produce edema, hemorrhage, necrosis and ulceration. These effects are most evident in the colon. Occasionally the ileum is similarly, though less acutely involved. Accompanying the swelling of the villi and the edema of the mucous membrane there are cellular exudation into the submucosa and degenerative changes of the muscular layers. It is improbable however that the changes which we have noted by roentgen and by tissue examination result from such a mechanism. The conditions found have been identical irrespective of the presence or absence of dysentery bacilli. There is a striking similarity in the roentgen changes found throughout the series, both ulcerative colitis and sprue.

Fig. 5—Collection of barium in groups of coils of the "hologna type." Isolated pocketing. Irregular distribution in intestine. Changes in segment in left iliac fossa.

colostomy, which rendered interpretation of the changes uncertain although gross abnormalities of this segment had been noted at the original operation. In the fourth case the pathologic picture is complicated by an extensive inflammatory reaction in the serosa secondary to a terminal peritonitis following perforation. No sections of the upper part of the small intestine have been obtained for study during life, since surgical intervention in this region has not been indicated.

Microscopic examination of the sections demonstrated edema of the mucosa and submucosa, and slight infiltration by mononuclear wandering cells and round cells in all four cases. Specimens from two other cases, which were not examined radiologically, showed similar changes.

The nature of the processes leading to these phenomena is obscure. Three different mechanisms may contribute. They may result from actual infection of the intestinal wall, they may depend on local allergy, or they may represent an effect of the deficiency state.

Evidence of infection by *B. dysenteriae* was obtained in three of four patients from whom sections were secured. Bacteriologic studies of cases of dysentery examined post mortem have shown the bacilli to be present throughout the intestinal tract.⁶ Soluble products of certain of these organisms when injected intra-

† No barium present in small intestine at the designated time.

irrespective of the bacteriologic background. This indicates that the alterations in the small intestine are not the result of a reaction to a specific group of bacteria. Furthermore, the type and the scantiness of the cellular exudate and the absence of degenerative changes do not imply an actively invading infection or excretion of an irritating necrotizing toxin.

Certain of the clinical phenomena suggest a sensitization of the intestinal tract to foreign protein. Sudden variation in symptomatology has occurred with alteration of diet or with autogenous vaccine therapy. Edema and smooth muscle spasm constitute the essen-

tial pathologic response to the so-called allergic reaction. Although such a process might explain some of the changes that we have described, it does not afford a complete explanation. Reduction in muscle tone rather than hypertonicity or spasm is one of the outstanding features revealed by x-rays in these cases. The clinical evidence also is contradictory. Many of the cases with advanced small intestine changes presented no indication of sensitization. Conversely, certain cases in which

that minor degrees of deficiency disease exist that find no place in current nomenclature.

Demonstration of the changes in the small intestine raises the two fundamental questions of their importance and their relation to the development of the deficiency syndrome. There is a definite correlation between the roentgenologic and the clinical observations in the clinical stage 3 cases. The parallelism, although less evident, continues in the second stage, but it is conspicuously absent in the cases still in stage 1.

It is evident from reference to the table that all cases of ulcerative colitis far advanced clinically show extensive changes in the small intestine. It is equally true, however, that there may be extensive involvement of this segment without demonstrable clinical evidence of deficiency disease. It is perhaps significant that identical changes were observed in the three cases of sprue although in two of them the disease was quiescent at the time of roentgen examination.

If these structural and functional alterations condition the development of deficiency states despite adequate diet, they must act either to inhibit normal elaboration of the diet substrate or to reduce absorption of the normal end products of digestion. In such an event the intestinal changes might be expected to occur before the functional impairment becomes evident clinically. Furthermore, in view of the storage capacity of the body tissues the appearance of clinical indications of deficiency disease need not coincide exactly in time

Fig 6—Movement by groups. Cessation of gastric peristalsis. Segments of intestine proximal and distal to filled area contain no barium. Mucosal irregularities in filled group.

such a process seemed to be operative showed no abnormalities on radiologic examination.

Abnormalities in the intestinal tract have been noted in experimental avitaminosis in animals. Gross⁸ found reduced motor activity in rats immediately after the withdrawal of vitamin B from the diet. Plummer⁹ reported that deficiency of this substance reduced the tone of the intestinal musculature and the amplitude, the rate and the length of time during which spontaneous contractions of an isolated segment occur. Similarly, Rose, Stucky and Cowgill¹⁰ observed diminished motor activity of the dog's stomach when the animals exhibited the effects of advanced deficiency of this vitamin.

The association of clinical evidence of deficiency disease and the changes noted roentgenographically suggests that a relative insufficiency of the antineuritic vitamin may underlie the reduction of tone and the depression of motor function in the intestine observed in these patients. The data at present available are insufficient to evaluate this possibility. The rarity of peripheral neuritis may be advanced as evidence against such a concept, yet it is becoming increasingly apparent

Fig 7—Irregularities of mucosal pattern, isolated pocketing. Note pattern of transverse loop at level of fourth lumbar vertebra.

with development of the underlying phenomena. The occurrence of intestinal changes in cases not showing deficiency symptoms therefore is not a fundamental contradiction.

The six cases in clinical stage 2 without abnormal conditions in the small intestine are difficult to account for, since deficiency signs were quite evident clinically. However, there are several possible explanations. The alterations observed by roentgenologic examination have been found to vary from time to time in the same

patient. In several instances, reexamination after the lapse of a few weeks has shown marked improvement, in others, progression of the process. In neither case have the intestinal changes been closely paralleled by obvious alteration of the clinical picture. It seems possible, therefore, that a temporary enteric derangement may be followed by delayed effects. Other variables probably enter into the production of the final result. Anorexia leading to reduction of the total food intake, fever and toxemia, which increase the physiologic requirements for specific substances, and the quantitative factor of reduction in intestinal function are all important in the production of contradictions.

It is impossible at the present time to state whether the small intestine changes are a factor in the production of the deficiency state or the result of such states. The association of the two in the same patient and the similar alterations observed in sprue suggest that these changes may impair absorption and thus contribute to the complex clinical picture of deficiency disease.

Fig. 8—Bizarre pattern of mucosal folds in duodenum and small intestine

CONCLUSION

1 Changes in the small intestine have been demonstrated roentgenographically in twenty-nine of thirty-seven cases of chronic ulcerative colitis and in three cases of tropical sprue.

2 The changes are those which could be produced by edema of the mucous membrane, disorganization of the normal motor activity, and reduction in tone of the intestinal musculature.

3 They are constantly present and most marked in the cases showing advanced deficiency states. In the milder cases the parallelism is not exact.

4 While the evidence does not warrant definite conclusions, the observations suggest that these changes in the small intestine are related to the deficiency states and perhaps play a role as a conditioning factor in their development.

ARTERIOGRAPHY

A ROENTGENOGRAPHIC STUDY OF THE PERIPHERAL ARTERIES OF THE LIVING SUBJECT FOLLOWING THEIR INJECTION WITH A RADIOPAQUE SUBSTANCE

EDGAR V. ALLEN, M.D.

AND

JOHN D. CAMP, M.D.

ROCHESTER, MINN.

The chief function of arteries is the transportation of blood. As far as the arteries are concerned, this function is dependent entirely on the size of and the presence or absence of obstruction of the lumens. The adequacy respectively of the entire arterial circulation of an extremity, and of its component parts, requires separate consideration. The situation is analogous to that which exists in the heart, the myocardium may function normally, even if the valves are functionally insufficient. In the extremities the arterial circulation as a whole may be adequate, even when some of its component parts are badly diseased.

There are many methods for determining the sufficiency of the entire arterial circulation to extremities such as studies of the response of the temperature of the skin to artificially induced fever, spinal anesthesia, and block of peripheral nerves; analysis of symptoms; effect of posture on the color of the skin of the extremity, and palpation of the larger peripheral arteries. These and other methods leave little to be desired in determination of the efficiency of the arterial circulation as a whole. This situation is sharply in contrast to study of any of the component parts of the peripheral circulation. Arteries, except large arteries, are not ordinarily visualized roentgenographically unless there is calcification of the walls, and even then no information can be gained regarding their caliber. Palpation of pulsations in an artery furnishes valuable clinical evidence of its functional integrity, but pulsations can be felt only in a large artery such as the dorsalis pedis, posterior tibial, popliteal, femoral, radial, ulnar and brachial. Edema and obesity interfere with palpation of these vessels, and pulsation may be absent at the usual site of an artery because of congenital variations as well as disease. The surmounting of these difficulties, and of those regarding function of the component parts of the peripheral circulation, lies in visualizing the arteries by means of a radiopaque substance injected into the lumens. In addition, by its use, information may be gained regarding the nature of pathologic processes and regarding methods of compensation for arterial occlusion.

Arteriography is almost as old as roentgenology itself, for Haschek and Lindenthal¹ reported the roentgenologic visualization of the arteries of an amputated hand and forearm following intra-arterial injection of a radiopaque substance, about eleven weeks after Roentgen discovered the rays. However, it was not until 1923 that the procedure was carried out on living subjects.² Earlier work concerning arteriography of

peripheral arteries has been reviewed by one of us³ and by Edwards, in addition visualization of the abdominal aorta and cerebral arteries has been reported by Moniz⁴ and his associates, by Lohr,⁵ and by dos Santos and his associates⁶

SUBSTANCES FOR ARTERIOGRAPHY

The ideal arteriographic substance is one which can be injected into an artery without producing pain, or immediate or delayed toxic effects, and which is of good radiopacity in spite of the unavoidable dilution by the blood after injection. Various substances have been used: iodides and bromides of sodium, strontium, potassium and calcium, proteinated silver salts, iodized oil, skiodan, diotrast, neo-iopax, emulsified iodized oil and thorium dioxide sol.² In most of our studies we have used thorium dioxide sol which consists of from 19 to 20 per cent by weight of thorium dioxide. This substance is distinctly superior and meets the requirements for an ideal arteriographic substance, except for the possibility of an immediate or delayed deleterious effect. The immediate toxic effects of small amounts appear to be mild, of little importance, and to occur rarely. The substance is under suspicion chiefly because of the possibility of delayed effects due to radioactivity. As stated in a review by one of us, thorium is a heavy metal with some radioactivity, and thorium dioxide is extremely slowly excreted from the body, probably requiring years to be removed completely.³ The possibility of eventual harm due to radioactivity can best be summarized as "suspected but not proved." Radt,⁷ who has had extensive experience, observed animals and human beings respectively three and a half and two years after injection of thorium dioxide sol, harmful effects were not noted. He expressed the belief that the possibility of harmful effects is largely negligible, provided correct amounts are used and contraindications to the use of thorium dioxide sol are observed. Thorium dioxide sol has been used in many hundreds of cases for roentgenologic visualization of the liver and spleen and ordinarily for this purpose about 1 cc per kilogram of body weight is necessary, although Erickson and Rigler⁸ have reported satisfactory results with smaller amounts. Excellent visualization of the arteries of the upper extremity can be obtained following intra-arterial injection of only 5 to 12 cc of thorium dioxide sol, the average amount of which is about 10 per cent of that ordinarily used for visualization of the liver and spleen. We have limited our studies largely to visualization of the arteries of the upper extremities, as larger amounts are needed for arteriography of the lower extremities. The dose used by us appears to minimize greatly, if not entirely to obviate, the possibility of harm. Erickson and Rigler, who have made extensive study of the possibility of harmful radioactivity of thorium dioxide sol, consider that a greater amount than that which we use is distinctly harmless.

TECHNIC OF ARTERIOGRAPHY

The Upper Extremities—The patient lies on the roentgenographic table with the film under the outstretched supinated arm. An ordinary sphygmomanometer cuff is wrapped about the arm as near to the shoulder as possible. Under aseptic conditions the skin and the tissues around the brachial artery, just above the lacertus fibrosus, are anesthetized with 1 or 2 cc of solution of procaine, 0.5 per cent.

The brachial artery is then entered with an ordinary venipuncture needle attached to a syringe containing the radiopaque material, as soon as the point of the needle is well within the lumen of the artery, and bright red blood pulses forcibly into the barrel of the syringe, the sphygmomanometer cuff is rapidly inflated above the systolic blood pressure and the radiopaque material is injected. The needle is quickly withdrawn and as pressure is made over the point of puncture to stop any transient leakage, the first roentgenogram is made. The sphygmomanometer cuff is now quickly deflated to the level of the diastolic blood pressure for a period of two to four pulse beats, to permit the injected material to be carried more distally. Then the cuff is quickly reinflated to its previous pressure, and the second roentgenogram is made. The procedure is repeated for a third film. The cuff is now removed, and with a gauze sponge firm pressure is made over the point of puncture for a few minutes. Additional films, with the forearm in pronation or in the lateral position, may be made before the cuff is finally deflated.

Fig. 1—Arteriogram showing the smooth outline and direct course of normal arteries. The collateral circulation is minimal.

The Lower Extremities—The skin and tissues about the femoral artery, just below the inguinal ligament, are anesthetized. The artery is punctured in the same manner as the brachial artery, the lumen is occluded above the point of puncture by pressure of an assistant's fingers, the medium is injected, and a film is exposed. The assistant lessens the pressure on the artery, allowing a small amount of blood to flow, and occludes it again by pressure while a second roentgenogram is made. The procedure is then repeated for a third film.

Difficulties of the Method—The radiopaque substance that is injected into the lumen of the artery is rapidly swept away by the blood, and adequate visualization of the arteries therefore depends on exposure of the film at the exact moment when the injected mate-

trial is present in the part of the artery that is to be studied. With some study and practice, the proper moment for exposure of the film can be determined accurately, and after some experience the technic of arteriography becomes relatively easy. Successful results demand the closest cooperation of the roentgenologist and completion of technical details with a minimum of delay, since the loss of a few seconds after the injection may result in failure. Difficulties arise when the arteries are small when they are deeply situated or when there is abnormal irritability of the artery, resulting in apparent spasm. Occasionally one feels pulsations disappear from an artery when the point of the needle comes in contact with it. Successful injection of the artery is difficult or impossible under these circumstances.

When the procedure is expertly carried out, the patient experiences little or no discomfort during the

Fig. 2—Smooth diminution in caliber of the ulnar artery and a similar increase to normal size due to spasm.

injection. A slight degree of soreness may occur in the injected area as the anesthesia wears away. A mild anodyne and the application of moist, warm dressings relieve this if necessary. Symptoms of a general nature are almost entirely lacking following the injection.

The patient experiences distress of any consequence only if some of the material is injected into the wall of or outside the artery. Considerable pain, redness and increased temperature occur locally. These symptoms and signs persist for from one to three days and are best treated by the application of hot, moist packs and an anodyne. No permanent effects have been noted, even when large amounts of the medium have been injected outside the lumen of the artery.

INTERPRETATION OF OBSERVATIONS

In the interpretation of roentgenograms of the peripheral arteries, one is concerned chiefly with (1) congenital variations from the usual formation of

the vascular system, (2) alterations in the lumens of arteries, consisting of irregularities in contour, diminution of caliber, and complete occlusion, and (3) the presence or absence of collateral circulation, and its situation and extent.

Care must be used in the interpretation of the roentgenograms, for apparent changes resulting from errors in technic of injection, or in timing of the exposure, may be erroneously considered as evidence of organic disease. The three roentgenograms made in the manner described should be studied together, for changes due to organic disease will be constant in each, while pseudodeficits due to technical errors will vary in extent and type in the various films.

As might be anticipated, normal variations in formation of the arterial system are many. Certain vessels that are sought by the clinician in the physical examination of patients suspected of vascular disease may be absent congenitally, or they may be smaller in caliber than usual. Information concerning their status, and also that of other arteries normally too small to palpate clinically, for example the digital arteries, is readily determined from the arteriogram and is of considerable assistance to the examiner in doubtful or borderline cases of arterial disease.

The normal arteriogram is characterized by (1) smooth and uninterrupted contour of the lumens of the injected arteries, (2) direct course of these vessels and (3) presence of no more than a minimum of collateral circulation (fig. 1). Ordinarily the lumen of an artery is fairly constant in size throughout its course except occasionally digital arteries, of which the caliber progressively diminishes distally. Not all digital arteries of the same patient are uniform in size, but usually they are approximately uniform. The size of the lumen varies in different subjects, and a small artery alone is not primary evidence of disease. Most normal arteries pursue a direct course, and any change in the direction of a normal vessel is ordinarily a gradual or rounded change in direction and not abrupt or angular. One common exception to this rule is the rather sharp angulation in the course of the digital arteries of individuals of middle or advanced age which we have interpreted to be evidence of arteriosclerosis, as it is not seen in normal arteries of younger subjects.

Spasm of a portion of an artery is characterized by smooth diminution in caliber to a point of complete or almost complete obliteration and an equally smooth increase in its size up to normal (fig. 2). This appearance may vary or disappear in subsequent films.

THE ROENTGENOGRAPHIC APPEARANCE OF DISEASED ARTERIES

Thrombo-Angitis Obliterans—The disease process, as shown roentgenographically in the upper extremities, is not uniform. Many phases of the process may be viewed in the same arteriogram, and arteries of normal appearance may be seen in close proximity to those that are extensively involved. There is no uniform tendency of the disease to progress in one direction, either proximally or distally, and one segment of an artery may be involved in a process varying from slight to extensive, whereas other segments of the artery may appear normal. A digital artery may fill normally while a companion artery is partially or completely occluded in the same comparative area. This patchy distribution of the changes is one of the characteristics

of the disease which most commonly involves the digital and palmar arteries. The disease occasionally may attack the distal portions of the ulnar and radial arteries, but the middle portion of these two vessels is infrequently involved.

Three phases of involvement of an artery, based on the degree of occlusion revealed by an arteriogram, may be noted. The primary phase is characterized by

Fig 3—Thrombo-angitis obliterans. The primary phase of involvement is revealed by a change in the smooth contour of the ulnar artery. The second phase is shown by marked reduction in the caliber and marked tortuosity of the lumen of the radial artery. As is frequently seen a large collateral branch is given off from the radial artery above the point of occlusion. The final stage of involvement is illustrated by complete occlusion of the palmar arch.

a simple change in the contour of a segment of an artery. Instead of being smooth, the contour is irregular and the lumen varies in size. The filling defects are usually rounded in contour (fig 3). In the secondary phase the shadow is shaggy and moth eaten in appearance. The lumen, which is greatly reduced in size, pursues an irregular and rapidly changing course and widens and narrows in an irregular manner. The channel may be divided in places as an island divides a stream, or it may be fine and twiglike (fig 3). We do not know whether these appearances indicate a stage in progressive occlusion of the artery or recanalization of an artery once completely thrombosed. In the tertiary or final phase, complete occlusion of the artery has occurred. A distal or proximal segment may appear normal, or the entire artery may be occluded to the point of its usual termination. The point of occlusion is not abrupt, as if the artery had been ligated or cut across, but rounded, with the convexity toward the occluded portion. Occasionally a fine twig, or portion of diminished opacity, may extend a variable distance into the occluded portion (fig 3).

Collateral Arteries—The development of collateral arteries is an attempt to compensate for occlusion of the main trunks. The size, number and course of these

vessels is remarkable. Our roentgenologic studies give no indication of the origin of these collateral vessels, but we assume that they are smaller arteries not usually seen in the normal arteriogram, which have enlarged to carry on the function of the occluded main trunks. We cannot exclude their development *sui generis*. Small collateral arteries are usually characterized by an irregular, tortuous course, the larger arteries may proceed as directly as the main trunks. Either may arise from the main artery at a right angle. A collateral branch may run parallel to an occluded segment of a main artery and thus may connect the uninvolved portions of an artery. Collateral arteries seen in extremities, where occlusion of the radial or ulnar arteries has occurred, may pursue their course for several centimeters and may themselves become involved by the disease. In an area where there has been extensive diminution of the arterial supply, the collateral vessels appear as numerous fine twigs pursuing irregular criss-cross courses. When the lower ends of the radial and ulnar arteries are occluded, the interosseous artery usually extends into the palm of the hand.

Arteriosclerosis—We have not studied cases of occlusive arterial disease due to arteriosclerosis, because such a condition is rare in the upper extremities. In a case of advanced arteriosclerosis, the radial and ulnar arteries were found to have extremely irregular lumens

Fig 4—Arteriosclerosis. The radial and ulnar arteries are shaggy and moth eaten in appearance and the lumens are reduced in size.

which were moth eaten in appearance and reduced in caliber (fig 4). Distal to the wrist the radial, ulnar and digital arteries were normal in appearance, except for increased tortuosity of the last named.

Aneurysm—We have had the opportunity to study one case of aneurysm of the popliteal artery. In this case the aneurysm appeared in the arteriogram as a regular saccular dilatation, surrounded by a rounded, soft-tissue shadow of increased density, which we inter-

puted as thrombosis (fig 5). A few days after our study, the pulsating mass in the popliteal space increased in size and the pain increased in severity. At operation, a ruptured aneurysm of the popliteal artery was found.

Arteriovenous Fistula—One case of arteriovenous fistula of the digital arteries and one of the arteries of the palm of the hand were studied. The arteriograms in these cases had three features in common:

Fig 5—Arteriogram revealing an aneurysm (A) of the popliteal artery. A surrounding soft tissue shadow indicating thrombosis may be seen (T).

(1) dilatation of the arteries leading to the fistula, (2) absence of normal filling of the arteries distal to the fistula, and (3) "pooling" of the arteriographic medium in the region of the fistula (fig 6). The detail in the areas of "pooling" could not be determined, the increased opacity to roentgen rays was irregular in degree and extent, giving the appearance of wet snowflakes adherent to a window pane. This roentgenographic appearance has not been noted in other conditions and seems characteristic of arteriovenous fistula.

COMMENT

In the last eighteen months we have performed arteriography in 100 instances. Some of the arteries were normal although arterial disease was suspected.⁹ Examples of thrombo-angitis obliterans,¹⁰ arteriosclerosis, arteriovenous fistula,¹¹ popliteal aneurysm,¹²

arthritis, scleroderma, Raynaud's disease and hypertension, were also studied. Our experience with the procedure in these cases leads us to believe that roentgenographic visualization of arteries in the living subject has great possibilities, since it is the only direct method of acquiring information about the function of specific arteries. The time is apparently not far off when most of the arteries of the living human being can be visualized roentgenographically, and we can only hazard a guess as to the value of such a procedure. It is well known that accuracy in diagnosis of diseases, and understanding of the physiology of the digestive, urinary and biliary tracts, received great impetus with the advent of methods for accurate roentgenographic visualization of these tracts. We doubt that arteriography will prove to be as valuable, but the procedure opens a field for study which doubtless will lead to greatly enhanced knowledge of the pathologic and physiologic processes in arteries, and in the tissues which they supply with blood. We do not feel that the procedure has been of great diagnostic value in cases of thrombo-angitis obliterans, aneurysm and arteriovenous fistula, since careful clinical, physiologic and pathologic studies have proved satisfactory in high degree in this regard.

The chief value of arteriography, in our opinion, lies not in the direction of diagnosis but in that of patho-

Fig 6—Arteriovenous fistula. The increased size and tortuosity of the arteries leading to the fistula, pooling of the opaque substance in the area of the fistula and absence of filling of the arteries distal to the fistula are well shown (previously published by Horton and Ghormley).

genesis. It gives information of inestimable value regarding the minutiae of arterial disease, information which can be secured in no other way. It is to be expected that the absence or presence of organic arterial change in Raynaud's disease, and the part played by disturbances in arterial circulation in scleroderma can be determined. In thrombo-angitis obliterans, the part played by collateral arteries and other adjustments to

impaired circulation are portrayed in a manner that leaves little to be desired. The mode of progression of the disease, and the compensation for it, are clearly outlined. These observations appear to hold true for thrombo-arteriosclerosis obliterans, although our experience with arteriography in this condition has been distinctly limited. In addition, the situation, extent and nature of aneurysms, arteriovenous fistulas and arterial emboli can be determined accurately by arteriography. Whether or not the method will add information of value to knowledge of the pathogenesis of arthritis, hypertension and other conditions remains with the future to determine.

ABSTRACT OF DISCUSSION

DR. URBAN MAES, New Orleans. I welcome the opportunity to speak on the work that Drs Allen and Camp have just reported. Gangrene of the extremities is always an important problem in a large public hospital, if for no other reason than that it carries a mortality, to use my own figures of about 40 per cent. That mortality depends on two fundamental considerations, the length of time the disease has existed and the degree of arterial disease present. On that latter factor depend in turn, two considerations: whether or not amputation is necessary, and, if it is, at what level it must be done. The higher the amputation, the more certain is one to operate beyond the limits of the disease, but against that certainty must be set a mutilation that is frequently unnecessary and a mortality that increases the nearer one approaches the trunk. Aside from the question of mutilation no factor that increases the mortality can be lightly passed over: particularly in patients whom senility and diabetes, alone or in combination often make very poor surgical risks. It is most important, therefore, for the surgeon to be able to determine the degree of arterial disease present, and, although many tests have been devised for that purpose, none of them have been uniformly satisfactory. With the introduction of arteriography, however, direct visualization of the arterial tree is possible and the surgeon knows at least three things he did not know before: the size of the individual vessels, the contour of those vessels and the existence or absence of an adequate collateral circulation. Dr Veal in our clinic has used this method in 150 cases of vascular disease, and the results in gangrene have been very satisfactory. Again and again he has been able to tell the surgeon that he could safely amputate at a certain level and a study of the amputated limb, as well as clinical observation of the patient after operation, has proved that he was correct. Furthermore, while it is too early to make definite pronouncements, we are very hopeful that observation over a longer period of time will prove that the reduction in the mortality of the surgery of gangrene, which we have already noted in these cases is due at least in part to the information we have gained from arteriography as well as to other factors. I would like to emphasize the apparent safety of stabilized thorium dioxide solution. We are using it in doses very much smaller than the dosage which the experience of others has proved to be safe. A series of experiments done in our school by Dr von Haam and Dr Tripoli has furnished us with laboratory confirmation of its safety. Their experiments show that the drug does affect the cells of the reticulo-endothelial system but that the cells which are destroyed are promptly replaced by normal cells, which function as perfectly as do the original cells.

DR. H. E. PEARSE, Rochester, N. Y. I don't think there is any doubt that the slides shown represent perfection in this method. Nor is there doubt of the desirability of arteriography. A discussion of the subject must center about the medium used. This involves consideration of its density, ease of administration and the harm that may result thereby. There are three types of substances available. The first is the unsaturated oils, such as iodized poppy-seed oil, which have the uniform disadvantage of possible fat embolism. The next group of compounds available are the soluble crystalline substances. It is universally true that the crystalline substances used for arteriography are in a hypertonic solution to secure sufficient density. One injects a strong hypertonic solution,

which invariably causes pain. It is in this group that Dr Warren and I have been particularly interested. We have tested many radiopaque substances of the crystalline group. We have been unable to obtain a substance that can be injected without pain. The third group is the insoluble particulate substances. These will affect the reticulo-endothelial system. I think this may be disregarded. There is ample experimental proof that one can inject particulate matter without influence on immunity. The factor of radioactivity is the one to be considered with thorium dioxide sol. It carries a negative electrical charge. It fogs a film if left for five or six days. If injected into a dog and the liver and spleen are taken out six months later, they in turn will fog a film. One may measure the radioactivity of this substance. The whole thing hinges on whether or not the amount used in arteriography is sufficient to cause delayed effects. That appears to be the salvation of the method. Thorium dioxide sol has a radium equivalent of approximately 125 micrograms per hundred cubic centimeters. How can one determine whether or not this will have a deleterious effect? The only comparable situation is that with the radium dial workers. A dose as low as 2 micrograms caused chronic poisoning. One introduces into the circulation a radioactive substance that will give internal irradiation over a long period of time. I think that the small amount used is the factor that makes the method safe. But this must be watched. One should not repeat the method sufficiently to raise the level of the dose up to that of the radium dial workers.

DR. IRVING WRIGHT, New York. At the Vascular Clinic of the Post-Graduate Hospital in New York we have had a limited but satisfactory experience with this method of diagnosis. Within the last several months a man aged 65, was in the wards with diabetes, with an acute infectious, rapidly spreading gangrene of the right first toe. The clinical experience would have indicated rather prompt amputation to save the patient's life, and the amputation would undoubtedly have been made high. Oscillometric readings showed no oscillations below the popliteal artery. There was considerable edema over the top of the foot, making it impossible to determine pulsation of the dorsalis pedis artery. We used the authors' technic and to our surprise found that the major arteries were open well down into the foot although they were somewhat narrow in the lower part of the leg at the point where the oscillometric readings could be made. On the basis of the major arteries being open and excellent collateral circulation being established, we had the courage to refrain from amputation for some time, and within a few days there was a sharp demarcation of circulation. We took care of the situation satisfactorily and the patient lost only the first toe. A second case illustrates a warning that might be uttered against too rapid amputation. This patient was seen by Dr Carl Green. There was occlusive arterial disease of the lower extremities. The arteriogram taken, according to the technic described here, showed apparently no opening of the major vessel below the femoral artery. The oscillometric reading was negative to that level. It was decided to repeat the arteriogram after first giving the patient spinal anesthesia and it was found that the vessels then showed clearly down to the level of the beginning of the dorsalis pedis artery. It seemed as though in that particular patient a reflex spasm upward had deceived us as to the exact level of the organic occlusion. If we had accepted the reading of the first arteriogram the chances are that the patient would have had amputation at a much higher level than was deemed necessary. Dr Allen and his co-workers are to be congratulated because, although other men have done this work abroad, they have been the men in this country who have interested us and inspired us to attempt this technic.

DR. E. V. ALLEN, Rochester, Minn. I am sorry that time did not permit an adequate review of the literature on the subject. The names of Drs Pearce and Warren are preeminent in this field, and their work has served as a model and as a stimulus. Experimental work that they have done has not been equaled so far as I know. Dr Maes and Dr Wright have brought out some of the clinical values of arteriography, which are extremely practical. Dr Pearce has stressed the point that the single contraindication to the use of thorium dioxide sol is a possibility of delayed radioactivity. Safety in the use of this substance appears to lie in the amount used.

In our studies we have used only about 10 per cent of that required for roentgenologic visualization of the liver and spleen, and from the best information we can obtain it would seem that this amount is entirely harmless. I am sure that all of us would be pleased if an arteriographic medium was available about which there was no question of possible harm following its repeated injection in the same patient. It is probable that such a medium will be produced in the future. When this is accomplished, I feel certain that the study of the peripheral circulation by the intra-arterial injection of a radiopaque substance will receive a great impetus.

THE RELIEF OF MENOPAUSE SYMPTOMS BY ESTROGENIC PREPARATIONS

ELMER L. SEVRINGHAUS, M.D.

MADISON, WIS.

Therapeutic use of ovarian preparations for relief of the symptoms accompanying the menopause has met with varying and unpredictable success until within the last few years. The production of estrogenic preparations in biologically assayed form was the occasion for substantial improvement in clinical management of these patients. In 1929 the first American report of dependable treatment of the menopause with such material was published.¹ Corroborative reports have appeared by Bowman and Bender² in the field of psychiatry, by Hamblen³ in gynecology and by Werner and Collier⁴ in internal medicine. Experience with several standardized ovarian preparations is now so widespread among clinicians that there can no longer be the doubt of the efficacy of treatment expressed by King⁵ in 1928. The usefulness of the estrogenic substance has been shown to extend not only to the commoner types of climacteric symptoms but also to the not infrequent involutional disturbances with frank psychotic manifestations⁶ and to the cases that may be called pseudothyrotic.⁷ There are likewise women in the climacteric who complain of gastro-intestinal disturbances and who benefit by this treatment. The aspects of disturbed metabolism for which the climacteric may be to blame have doubtless not been exhausted by this listing.

Among the clinical problems of importance are the duration of treatment, the dosage required, the relative value of different methods of administering the hormone, the choice of commercial preparations with least cost to the patient, and contraindications to the use of estrogenic preparations. Data bearing on these questions are secured from the study of 115 cases that I have seen, ninety-five of which have been treated. Statistical treatment of the results is not warranted by

these numbers. Important clinical impressions may be secured, however, from these histories.

The results as well as the complaints are largely subjective, but clinical experience with estrogenic preparations for the menopause complaints has gone beyond the point at which their efficacy can be considered due to suggestion. Evidence of improvement is in the patient's report of relief, sometimes amplified by the observations of the family or friends as to return toward her previous mental and emotional status. In spite of this predominantly subjective nature of the material one must deal with it, for this is what patients continually ask relief from. Essential uniformity of relief by different preparations, given by different physicians and maintained after removal from contact with the physician, is hard to reconcile with any other explanation than an organic alteration in physiologic processes. The mechanism of the action cannot be explained with certainty. It seems increasingly probable that the fundamental factor is inhibition of action of the anterior pituitary, temporarily released from normal check by the ovary, until the time arrives when a stable balance of this and other endocrine glands has been reestablished.⁸

DURATION OF TREATMENT

The natural history of disturbances due to the climacteric—spontaneous or induced—apparently can include periods of autonomic, emotional and psychic instability varying from a few days to nearly two decades. There is no known way to predict the length of this period in a given case. Hence any statement that therapy alters the duration of the symptoms must be based on large numbers of cases, statistically analyzed, which is out of the question at this time. There is no control series available, but the experience of the past six years with this material has failed to reveal any woman who required treatment lasting longer than two and one half years. In a number of severely disturbed cases relief has been maintained following shorter periods. This encourages the belief that therapy not only reduces the symptoms but shortens the course of the disturbance. The history of a case will illustrate some of the features of this problem.

M. S., aged 24, had the removal of the last portions of ovarian tissue at the seventh laparotomy she had had for relief of appendiceal infection, adhesions, and follicular cysts of both ovaries. The menses never reappeared. Theelin was given, 50 units daily hypodermically beginning ten days after this operation, when typical climacteric symptoms were markedly in evidence. This was inadequate, but it was replaced successfully by 400 units of theelin orally each day. Another obstruction necessitated laparotomy and the therapy was interrupted for a few weeks, at which time symptoms were in abeyance. Return of the complaints led to resumption of the use of theelin, the dose of which was reduced gradually to 50 units daily. Then amniotin in oil solution was given in the same dosage with identical results. The doses were still further reduced to three and then two times weekly and stopped after nine months total therapy. Symptoms appeared again with summer weather about three months later, and the dose required to stop discomfort was 100 units of theelin or of amniotin oral. This was replaced shortly by 50 unit doses of amniotin in oil, injected hypodermically on alternate days. The dose was gradually reduced in frequency, replaced by amniotin oral and all therapy stopped twenty months after operation. There has been no significant return of menopausal complaints in the three months since, and the patient has been increasingly active during the past year.

In three other young women who have been subjected to complete oophorectomy the progress from

need of large doses to freedom from symptoms without therapy has required from three to ten months. It is impossible to establish a rule from four such cases. It has been evident in all these women that progressive decreases in dosage were possible without sacrificing relief from discomfort. In four other women with an artificial menopause, three produced by irradiation, a similar decrease in dosage is being carried out, with promise that less than two years of continuous therapy will be required. As compared with the few patients who have not remained under treatment but who were temporarily relieved while still in the hospital, it appears that this type of endocrine therapy is responsible for abbreviating the disturbance of the artificial menopause. A similar gradual reduction of doses and amelioration of symptoms is observed regularly in those women with a spontaneous climacteric. It would be wrong to give the impression that a definite duration of symptoms or of treatment can be stated. However, the assurance that treatment has a finite period puts this endocrine therapy on an encouraging basis as compared with that necessary for myxedema, diabetes or adrenal insufficiency, i. e., the organism can reestablish a balance after the menopause.

DOSAGE REQUIRED

In the use of follicular hormone the dose must be made adequate for the effect desired. There is no way evident in which this may be predicted for a given patient. Occasionally 10 units daily by the hypodermic route will be adequate. Far more frequently the initial week will be only partly successful unless from 25 to 50 units is given each day. Larger doses have been required at first for the control of symptoms following immediately after oophorectomy in women younger than 40. As a guide to the adequacy of the dose, it may be suggested that results are to be expected in terms of days rather than of weeks. One need not be satisfied with anything short of complete relief of all the vasomotor and emotional disturbances. The amount may as well be increased promptly to this point of complete restoration of comfort, following which reduction is to be tried gradually during the following weeks. Reappearance of hot flashes, insomnia and the like calls for an increased prescription. If no symptoms appear for some time it may be well to omit treatment for a few days to determine whether it is still needed.

There is little evidence that two daily injections are more helpful than one. If in the early stages treatment is given less than once daily, relief may not be continuous, which indicates too infrequent administration of the preparation. Later it may be possible gradually to reduce the frequency to alternate days, twice weekly, and then to omit it entirely. Some women find that symptoms may remain quiescent for some weeks, to return under excitement or exposure to heat. Relief is secured within a day or two when daily use of the material is resumed.

RELATIVE VALUES OF VARIOUS PREPARATIONS

An attempt has been made to evaluate the different commercial preparations of standardized estrogenic substance in use in the United States.*

* Squibb's amniotin has been used in aqueous solution hypodermically in hardened gelatin vaginal suppositories in oil solution orally and in oil solution hypodermically. Parke, Davis & Co.'s theelin has been given in aqueous hypodermic solution and in vaginal suppositories and theelol has been given in tablets and capsules orally. Progynon produced in Germany by Schering and imported by the Schering Corporation has been used only in the tablets orally. For much of this material I am indebted to Dr. J. F. Anderson of E. R. Squibb and Sons and to Dr. E. A. Sharp of Parke, Davis & Co. A preliminary supply of progynon was also furnished by the Schering Corporation.

In 1929 Sevringhaus and Evans¹ reported activity of the gelatin suppositories. These were as effective as the hypodermic injections if the dosage was about three times as large. This form of treatment has no longer anything to recommend it, since oral administration is possible at no greater cost.

Numerous comparisons of the results from hypodermic injection of amniotin or of theelin leave no doubt that they are interchangeable, unit for unit. Difficulty was encountered at first when the preparations were not so uniformly stable or always standardized by the usual technic. Since theelin is now standardized in the same way, it is directly comparable to amniotin.

Several women who have demonstrated their cooperativeness have been invited to try the various preparations to determine their relative value. They have not known the supposed equivalent figures but have been assisted in determining the minimum dose of each preparation that would duplicate the relief from symptoms achieved by previous materials. To avoid being misled by decreasing need for treatment it has been necessary to return occasionally to the previous form of treatment to check the need. The clinical details previously cited in the treatment of a case of artificial menopause showed the essential equivalence of theelol and amniotin oral, given by mouth. In the same case it was found that hypodermic administration of amniotin in corn oil was between four and six times as effective as the same number of units orally. A further protocol will illustrate the method of trials.

M. N. had two children, and following a few months after the second delivery, at the age of 20, a perfectly typical spontaneous menopause occurred. Symptoms had continued for seven years before she was referred for treatment. At that time she was in a moderately severe involutonal psychosis, unable to care for her children. Improvement was prompt and continuous, almost dramatic to the social workers who assisted. After two and a half years of continued treatment she has gone six months without caring for any further therapy and has for two years been responsible for all her home duties.

At first she received amniotin hypodermically, 20 units daily. After a number of weeks this was changed, and she found that 90 units of progynon orally was about as satisfactory. Theelol, 100 units daily, was a little more helpful. This suggests that the oral dose needs to be between four and five times the hypodermic dose. Next an attempt was made to stimulate her ovaries with antutrin-S and with follutein (commercial preparations of the anterior pituitary-like gonadotropic stimulating substance from the urine of pregnancy), but no flow and little subjective benefit resulted.

Next a comparison of theelol and amniotin oral was made. At this stage she found that 400 units of theelol gave excellent results but that 200 was inadequate. She thought that 200 units of amniotin was inferior to the same dose of theelol, but at 300 units the judgment was reversed. Improvement began to be manifest, and the dose was reduced to 100 units. Comparisons of theelol and amniotin at this level and at 150 units were in favor of the theelol, but the advantage was found to be the tastelessness of the theelol tablet or capsule as compared with the unpleasant odor of amniotin which she could not easily disguise.

For some reason her requirement seemed to rise, and control was secured by from 200 to 300 units of amniotin oral. She then changed to the use of amniotin in oil given hypodermically. She was trained to give the injections herself. With this material she found that 50 units daily gave as much relief as 300 units of amniotin oral. This 6 to 1 ratio is probably significant of a slight advantage of the oil solution as compared with the aqueous hypodermics in the same patient earlier. After four months she began to reduce the frequency of doses and by the end of thirty months of total treatment she was able to stop all use of ovarian hormone.

Similar trials with other women have shown an advantage sometimes for one preparation, sometimes for another. It was evident at times that the disagreeable taste of amniotin oral was a handicap to the comparison. Some women disguised this readily in food and at times reported it as superior to theelin. In general, the impression is gained that there is no dependable difference in therapeutic efficiency between the same number of units of amniotin oral, of theelin and of progynon. Also the oral dose of these materials appears to be about five times as large as for the hypodermic administration. These impressions are gained from the treatment of ninety-five women, seven different preparations being used with an average of two preparations per patient.

The use of the oil solutions hypodermically is of interest. The only one tried was amniotin prepared in a refined corn oil. This caused no local pain and was apparently well absorbed even when used for a period of months in the case just cited. Two women who used it had an impression that it gave a more sustained effect throughout the day than they noted from single doses of aqueous hypodermic material. This is hardly sufficient evidence to be dependable, the difference is certainly slight. In one woman who used this material a severe local reaction developed at the site of injection and hay fever and asthma appeared simultaneously during the corn pollen season. She was then found to be allergic to corn pollen and knew that exposure to corn at certain times caused hay fever and asthma. A sample of the corn oil supplied by Dr. Anderson failed to give typical skin reactions, but there was an immediate and very transient reaction to the amniotin in skin testing. The entire episode was atypical in that local reaction to the oil injections did not appear until after several weeks of its use. In general the use of the oil solution has no obvious advantage, although it has less risk than is usually assumed.

COST TO THE PATIENT

It will be apparent that oral therapy is so dependable that it should be the method of choice. About five times as much needs to be given as by hypodermic injection. But in the case of amniotin the oral preparation is priced so that there is no differential to interfere with the oral use. Unfortunately, theelin costs at least 50 per cent more than the equivalent dose of theelin. There is only a little difference between the cost of the theelin and amniotin used hypodermically. But in the case of progynon the tablets cost much less than the equivalent dose of any other preparation. It is greatly regretted that the American products have not been available at prices that justify their preference or at least their being on a parity with the imported material.⁹ At the most recent quotations it would seem the duty of the clinician to protect the interest of his patients by prescribing the least expensive preparation. Cost of treatment is practically the only reason assigned by patients who have stopped treatment while symptoms persisted. Since there is no advantage to the use of hypodermic materials, the cost of professional service for their administration or the trouble of teaching the patient the technic should operate to secure the early and entire replacement of this method of medication by oral therapy.

⁹ Since this manuscript was prepared I have learned that the American products will be markedly reduced in retail cost shortly. Purchase may therefore well be made on a basis of cost per unit and type of medication desired.

CONTRAINDICATIONS

There are two situations that call for a reduction in dosage. One is the occurrence of a vaginal bloody flow. In several cases this has occurred during the therapy, as reported by Werner and Collier.⁴ There is no serious harm, but it is wise to reduce the dose. Control of symptoms has been achieved with doses less than enough to cause a repetition of bleeding. The other circumstance is the stimulation of libido to an uncomfortable degree. There is no doubt that the estrogenic principle is not only estrogenic in animals but also the important biologic factor arousing libido in women. One woman, aged 30, who had suffered oophorectomy at 21 and hysterectomy at 25, was doing very well while using 50 units of amniotin in oil hypodermically. During a trip she became conscious of an unpleasant increase of general sex interest and libido. Suspecting the medication as a possible cause she reduced the dose sharply, with much relief.

In addition (although this may appear paradoxical at first glance) it is probable that primary amenorrhea or any condition in which it is desired to reestablish absent menses should be a contraindication to the use of this hormone. The use of large doses of estrogenic substance is known to cause inhibition of the anterior pituitary factor normally responsible for stimulating gonadal development and activity. Therefore, although estrogenic preparations given in large doses may substitute for the ovary in stimulating a uterine development sufficient to be followed by a flow, this result is only temporary, and the ovaries themselves are left less active than before therapy. The commercial producers advocate the use of the material for these cases. There is reason, based on the results obtained in lower animals, to consider this entirely erroneous. Such cases really require stimulation of ovarian function through pituitary medication.

SUMMARY

Observations made in following the course of treatment of ninety-five women suffering from menopausal disturbances indicate that the sustained use of adequate amounts of estrogenic substance tends to shorten the course of the disturbance. In no case has therapy been needed longer than thirty months. The daily dose required varies and must be determined by trial. The criterion suggested is the minimum that secures complete relief from the autonomic and emotional disturbances. There is no clinically significant difference between the same number of units of the different preparations—amniotin, theelin and progynon—when they are administered by the same route. Oral therapy is so dependable that it may well replace hypodermic administration. The choice of preparation used may be made on a basis of cost, provided any one of the biologically standardized preparations is employed. Contraindications to the use of estrogenic preparations include reestablishment of menstrual flow after the menopause, undue increase of libido (both of these calling for reduced doses) and amenorrhea in cases in which it is desirable to restore menstrual function.

ABSTRACT OF DISCUSSION

DR. EMIL NOVAK, Baltimore. Many women pass through the menopause with scarcely any symptoms so that they need no treatment. In a large number the symptoms are rather mild, so that no treatment is necessary except an instructional and reassuring talk from the medical adviser as to the normality of the symptoms, their temporary nature, the importance of avoiding stress and anxiety and perhaps the administration of

some such simple nerve sedative as the bromides. In a minority of cases, however, the characteristic symptoms, and especially the vasomotor flushes and sweats are so pronounced and disturbing that efforts at organotherapy are called for and I know of no rational plan other than the employment of the only potent ovarian hormone available. I refer, of course, to the follicle hormone, usually in the form of theelin aminotm or progynon. Why is this plan rational? That the menopause is produced by the withdrawal of the ovarian secretions is universally accepted. That the ovarian hormone responsible is estrogenic substance is indicated by considerable evidence. For example, hormone studies, especially by Zondek have shown that the woman passing through the menopause goes first through a phase of excessive production of estrogenic substance, then through one of deficiency in estrogenic substance and finally through one of excessive production of the gonadotropic factor. In the first of these menstrual excess is common but, in my experience, women with such functional bleeding rarely suffer with vasomotor symptoms. It is in the stage of deficiency in estrogenic substance that vasomotor phenomena are most common. Although little is known of the mechanism of their production, it seems probable that the most characteristic symptoms, the flushes of the head neck and upper part of the thorax, must be in some way evoked through association between the endocrine organs and the nerve centers, probably in the hypophyseal region. That withdrawal of estrogenic substance is the immediate cause of menopausal symptoms is further indicated by the fact that the removal of certain tumors that produce it in large amounts and, so far as is known, only estrogenic substance, may produce characteristic menopausal symptoms even in elderly women. In other words, women who have passed through one menopause at the usual age may experience a second many years later. I have recently reported such a case, and others have been observed by Schulze and Dworzak. For such reasons as these I look on substitutional estrogenic hormone therapy as rational. I am in essential agreement with Dr Sevringhaus as to the matter of dosage. As to the route of administration, for the present I prefer the hypodermic method in most cases, although it seems possible that a lowering of the expensiveness of commercial preparations will make the oral method the popular one in the future. I have not been able to understand why the commercial preparations of the estrogenic hormone are so expensive in this country and so cheap in Germany.

DR. J. P. PRATT, Detroit. The author has presented logically the treatment of an important group of clinical cases. It remains to be seen whether he is dealing entirely with a cause and effect relationship or has underestimated his psychotherapeutic results. Nearly ten years ago just after Allen and Doisy standardized the estrogenic hormone and purified it to such an extent that it could be used for injection into human beings I was impressed with the analogy between the human castrate and the animal castrate. The logical deduction was that an estrogenic substance that would completely substitute for the function of ablated ovaries in animals would do the same in man, the typical human castrate being of course one in whom the ovaries were removed at operation or a woman at the menopause. At that time a number of patients were injected with a preparation furnished by Allen and Doisy. Only a few units of a hormone were used but in the first twenty five cases treated the results seemed satisfactory. Then it was realized that the human experiments were not analogous to the animal experiments, for the estrous cycle and the menstrual cycle are quite different and in the human being no controls were being used. When other inert injections were used such as salt solution or sterile water equally good results were obtained. In other words, the first effect must have been largely psychotherapeutic and to a very little extent a relation of cause and effect. This has led me to question similar results without adequate controls. It would seem that in presenting a problem of this sort a series of controls should be maintained and a group of ninety-five patients should be sufficient to provide ample controls. The author's attempt to increase knowledge of human endocrinology is highly commendable. The brilliant laboratory achievements resulting from carefully planned and controlled experiments are most stimulating. The clinician's task is difficult. He deals with few normals but

has a wealth of material illustrating aberrations of function. Information can be obtained only in fragments and pieced together as well as possible. Conservatism is necessary, that clinical endocrinology may be established on a sound basis.

DR. E. P. McCULLAGH, Cleveland. There seems little doubt that menopausal symptoms are largely a matter of disturbed body chemistry. The symptoms appear regularly, not only at the time of the natural menopause but after irradiation of the ovaries and after oophorectomy. In addition, the symptoms are accompanied frequently by certain anatomic changes such as weight gain with distribution of fat especially over the trochanters, and a tendency to hirsutism. There are still other changes, such as a lowering of the basal metabolic rate, and bioassays show that there is definite disturbance in the levels of the various hormones. The mechanism of the production of menopausal symptoms must still remain in doubt. In certain individuals, at least during a part of the menopausal cycle there is an excess of estrogenic substance in the blood and urine. In others there is a rather marked excess of the gonad stimulating factor in the blood and urine. For this reason I was inclined previously to look on the menopausal symptoms as caused by an increase in gonadotropic substance rather than due directly to deficiency of estrogenic substance. This, however, I have not been able to show in all instances, which may be due partially to inadequate methods of assay. The mechanism of the climacteric may be better understood after methods of assay have reached a higher point of accuracy. It seems probable that the pituitary gland plays a large part in the production of menopausal symptoms and that it is likely that other pituitary hormones in addition to the sex factors are markedly disturbed. The frequency of occurrence of hirsutism, of hyperthyroidism, and of diabetes mellitus at this age lends support to this belief. In the relief of menopausal symptoms, the treatment is chiefly a matter of dosage, and there seems to be no advantage in giving doses oftener than once a day or in some instances once every second day. I have not been able to determine that relief is obtained more quickly by more frequent administration provided the dose is adequate. I believe the relief will be attained in a matter of days rather than weeks. There are still a number of cases in which therapy with estrogenic substance does not produce adequate improvement. This still may be a matter of dosage, but in my experience, even with doses that are adequate in relatively severe cases some patients fail to respond. It is difficult to judge from the patient's symptoms the relative value of estrogenic substance in any form after one course of treatment. Some patients with relatively severe menopausal symptoms after treatment for a few days or weeks can be completely rid of symptoms for months or the symptoms may not return at all.

DR. J. I. HOFBAUER, Cincinnati. The menopause is characterized by a definite increase in the number of the basophils in the prehypophysis. In 1922 the treatment of menopausal symptoms by irradiation of the hypophysis was introduced. I am still inclined to consider this method the best, as far as the results obtained are concerned. My views are shared by the reports of a good many clinicians. J. A. Huet, *Bull. et mem. Soc. de radiol. med. de France* July 1933, the Mayo Clinic, Sahler et al. No harm is done to the brain by this type of irradiation. Following the irradiation of the hypophysis in cases that showed definite signs and symptoms of hyperthyroidism, these symptoms disappeared, and the thyroid showed a marked decrease in size (*Arch. f. Gynäk.* 120). Recently, I treated menopausal symptoms with insulin in several cases, with somewhat gratifying results. I am anxious to learn whether there has been any study made concerning the absorption of ovarian hormones from the intestinal canal, since my observations have shown that anterior pituitary preparations are quantitatively destroyed by pancreatic juice.

DR. ELMER L. SEVRINGHAUS, Madison, Wis. I have no data on absorption of estrogenic substance taken orally, but the material is effective orally in doses five or six times as great as those given hypodermically. This ratio may indicate poor absorption or partial destruction. Several diabetic women failed to get relief from menopausal symptoms by the use of diet and insulin alone. The addition of estrogenic material accomplished clinical relief. It appears that insulin is useful only for the control of the diabetes. Although on theoretical grounds

irradiation of the pituitary should give relief from menopausal symptoms, I do not favor its use because it is as yet impossible to control the dosage so that other structures and functions are not also endangered. The replacement therapy is more physiologic and less precarious. The resistant cases in my experience have been the younger women with artificial menopause. The requisite doses are very high, sometimes as high as 400 units daily by hypodermic injection for a few days until control is established. After that the requirement rapidly declines. So far I have not seen any patient in whom I was unable to secure fairly satisfying relief. This tendency to improvement under therapy makes it necessary, when comparing two preparations, to return to the original one at times to find whether the need has decreased. This has been done in my series when there was any evidence suggesting that one preparation was more successful than another. The matter of control observations has been dealt with in previous papers. Experience has also been had with the same clinical group with unstandardized ovarian materials in previous years, when results were sometimes secured but the therapy was not dependable. Trials of bromides and barbiturates to reduce costs have also served as a control on the effectiveness of the therapy. Psychotherapy is admittedly helpful in making an approach to these women, but it is far from a complete therapy. Principally it can reassure by emphasizing the temporary nature of the climacteric. The cost of treatment could not be a disturbing factor in the results I have reported because the materials were furnished for most of these patients free of cost. I maintain that, for extended therapeutic procedures like this, the lowest cost to the patient is the optimum for the physician. More patients will come under treatment because increased availability will make for wider benefits and hence larger demands. Eventually retail costs are further brought down by quantity use. It is fortunate that the American manufacturers are viewing the matter in this light and already reducing prices.

USE OF THE ELECTROSTETHOGRAPH FOR RECORDING HEART SOUNDS

PRELIMINARY REPORT

WALTER L. BIERRING, M.D.

H. C. BONE, M.D.

AND

M. L. LOCKHART, B.S.

DES MOINES, IOWA

Our purpose in this report is to record the use of a new device for photographing heart sounds. The electrostethograph,¹ designed by M. L. Lockhart, appears to have certain advantages over other types of apparatus used for this purpose. A brief presentation of the historical background in the development of this field of investigation may be of interest.

According to Hirschfelder,² the first method for recording heart sounds was introduced by Donders in 1856 and was revised by Martius in 1888. It consisted of beating the time of the sounds on a receiving tambour and recording the movements of the lever.

Hürthle in 1893, Einthoven and Geluk in 1894 and Holownski in 1896 were the first to employ methods in which the sounds were received by means of a microphone.³ Hürthle received the sounds by a stethoscope connected with a resonance apparatus, which magnified the amplitude of the vibrations, the enlarged vibrations acted on the handle of a wooden tuning fork, the latter being set into vibration in the same tempo. The vibra-

tions of the arms of the fork excited the microphone, which set in action an electromagnetic signal apparatus, the movements of which were transferred to a pantograph of Marey and registered. Einthoven and Geluk picked up the sounds with the stethoscope and conducted them through a rubber tubing to a microphone. The currents were then led through a capillary electrometer the movements of which were photographed.

Fig. 1—Schematic diagram of the electrostethograph

Holownski also used a microphone as a receiver of the heart sounds but recorded them with the aid of a so-called optical telephone. The method depended on an application of the interference rings of Newton, the changes in the rings being then photographed.

Marbe in 1907 and Roos in 1908 used an entirely different objective method for recording the heart sounds. They transferred the oscillations of a tambour activated by the heart sounds to a gas flame of great sensibility. They applied the tambour over the chest and then passed a paper through the sooty flame, recording the sounds on this paper. Weiss and Frank devised instruments in which no microphone was used but in which the vibrations of a membrane set in motion by the heart sounds are magnified and recorded photographically. Otto Weiss first reported his work with this apparatus in 1907, and in 1908 Weiss and Hofbauer reported photographing fetal heart sounds.

An important step in the photography of heart sounds was developed in 1903 by Einthoven, who at that time introduced the string galvanometer.⁴ Einthoven's work resulted in an apparatus of extreme sensitivity, and easily applicable to clinical and physiologic research.⁵ Since the introduction of the string galvanometer in place of the capillary electrometer, Einthoven's method has passed into everyday use and excellent records of normal and abnormal heart sounds have been obtained. Using this method, Einthoven, Eyster, Kahn, Lewis, Bull, Fahr and others have contributed many accurate studies of the time of onset, duration and crescendo or decrescendo character of the normal and pathologic heart sounds and murmurs and have described variations with rate, respiration, posture and exercise.

In 1910 S. G. Brown introduced a telephonic stethoscope that amplified the heart sounds about sixty times. It depended on passing the sound currents through a telephonic relay, thereby increasing their strength.

Submitted for publication Aug. 31, 1934.

¹ Arrangements have been made with the Cambridge Instrument Company, New York, for the manufacture of the electrostethograph.

"Long distance" auscultation was then introduced and graphaphonic records were made that could be reproduced

In 1920 Dr H B Williams of New York⁵ used an electromagnetic transmitter and two stages of electrical amplification to record a cardiac murmur. Gen George O Squier of the U S Signal Corps at the same time amplified the heart sounds and reproduced them with a magnavox loud speaker for demonstration to assemblies and for long distance transmission. In an article published in 1922, M J Myres⁶ called attention to the use of the newly developed vacuum tube as a means of magnifying the electric waves of a telephone circuit and stated that in his opinion it was the beginning of a "microscope" for the ear.

In June 1923 Richard C Cabot⁷ reported the use of the electrical amplifying stethoscope, the result of three years of experimental work. The instrument was designed by the New York engineering department of the Western Electric Company and consisted of an

Fig 2—Complete electrostethograph unit

electromagnetic transmitter to pick up the sound, the current was then passed through three amplifying vacuum tubes, the last of which was the power or output tube. The current was then distributed to the receiving sets. The details of this device were published in 1924 by Gamble and Replogle.⁸ Later these workers used the electric filter⁹ to attain selectivity in the frequency of the vibrations introduced into the amplifying circuit. In February 1923 Jacobsohn⁹ of Germany reported using a similar amplifying stethoscope. More recently A Graham Asher¹⁰ of Kansas City has used the argon tube to record heart sounds. With this method the sounds are picked up by a microphone and after amplification the current is passed

through the argon tube, causing the glow of the tube to vary according to the current introduced. These variations in the intensity of the light are then recorded on photographic paper.

Valuable contributions on the subject of heart sound records and their interpretation have been made by Gerhartz, Battoerd, Joachim, Selenin, Hoogerwerf, Abbott, Duchosal, Wiggers and Paul D White. A

Fig 3—Normal heart sounds. Tracing on a man aged 32 no organic heart disease no audible abnormal sounds

Fig 4—Mitral regurgitation in a man aged 30 diagnosis rheumatic heart disease mitral regurgitation

number of these men as well as more recent workers have made simultaneous heart sound records and electrocardiographic records and have pointed out the advantages of taking the two records at the same time.

The electrostethograph was designed and built by M L Lockhart, it is illustrated in the accompanying schematic diagram (fig 1). This diagram shows sound waves being picked up by a microphone and amplified to the desired magnitude by a vacuum tube amplifier. These amplified sound waves, which have been changed to pulsations of electrical energy, are then fed into the moving coil of a d'Arsonval type of galvanometer. This coil of course, follows each electrical pulsation trans-

Fig 5—Systolic gallop rhythm in a man, aged 43. G is the extra sound. Diagnosis no organic heart disease

Fig 6—Mitral stenosis in a woman aged 53. Diagnosis rheumatic heart disease mitral stenosis partial decompensation

mitted into it. A tiny concave mirror attached to the moving coil in the galvanometer reflects light onto a moving photographic paper or film. Part of this reflected light is thrown on a ground glass screen, which enables the operator to observe the sound vibrations that are being photographed. Provision is made also to enable one to hear the sounds simultaneously as they are seen and photographed. A loud speaker may be used for group demonstration or classroom instruction.

The electrostethograph is operated entirely from the ordinary 110 volt current. It weighs 33 pounds complete and measures 18 inches in length, 7 inches in width and 9 inches in height. It is, of course, portable.

Owing to the use of a new type galvanometer in a unique circuit design, the necessity for calibration, standardization and focusing has been eliminated. The machine is simpler to operate than a modern radio set. The procedure is as follows: After the machine has been connected to an electric plug, the microphone is placed on the chest over the heart and the volume increased to the desired magnitude by the turning of a dial. To take the picture the operator has only to press a button, thereby starting the electric motor, which drives the film or photographic paper past the beam of light and into a light proof container. The technique required in placing and holding the microphone is the same as that required in the proper use of the stethoscope. The viewing screen is 60 mm in width, the same as the film, this makes it possible to determine accurately the dimensions of the finished picture. Murmurs and other irregularities can be seen as well as heard and the volume increased to bring them out with the desired magnitude on the picture. The value of this viewing screen cannot be fully appreciated until one uses it.

In the clinical use of the electrostethograph we have been impressed with the accurate reproduction of both normal and abnormal sounds audible to the ear. In making tracings it was advisable to suspend respiration during the time a record was being taken. This precaution was quite essential to take a satisfactory record

improved the quality of the tracing, since the interval between the heart sounds would be maintained free from oscillations. With high amplification, some oscillations of the base line were unavoidable. Intestinal borborygnus caused a rather marked disturbance in tracings taken over the lower part of the chest. In some records, definite oscillations were present for which we were unable to offer an adequate explanation.

Fig 8—Record with improved apparatus showing normal heart sounds

Murmurs audible to the ear were adequately photographed on our record. The murmur of mitral regurgitation was often relatively high pitched and did not make as prominent an excursion on the tracings as the intensity of the sound to the ear would lead one to anticipate. Thomas Lewis¹¹ as well as others have previously made this observation. In some cases with mitral regurgitant murmurs a short presystolic oscillation of the base line was present when no distinct sound was audible to the ear. On the tracing it was easy to decide whether a murmur was systolic or diastolic in time even with increased heart rates. The oscillations in mitral and aortic stenosis were large and relatively widely separated, while those in the regurgitant murmurs were more likely to be small in amplitude and less widely separated.

In photographing the heart sounds, both normal and abnormal, the visible impulse on the screen was exceedingly valuable in helping the operator apply the microphone in the optimum location and with the proper degree of pressure to bring out the sounds to the best advantage. It was also of distinct aid to the ear in recognizing adventitious sounds, particularly those of short duration. The deflection produced by the sound might be perceived on the screen before it was heard by the ear. The relative length of time occupied by systole and diastole was usually appreciably different to the eye, so that by watching the impulse one might see that a murmur was definitely systolic or diastolic in time. Audible splitting or reduplication of the first or second sounds always appeared distinctly in the photographic record. In gallop rhythm the extra sound was always visible on the photographic record and its location in the cardiac cycle was evident. In one case

Fig 7—Maternal heart sounds, maternal souffle and fetal heart tones in a woman aged 38. Diagnosis: pregnancy eight months.

over the base of the heart. The degree of pressure with which the microphone face was applied to the chest wall was an important consideration. The lightest pressure with which it was possible to maintain adequate contact with the skin and keep out extraneous sounds was most desirable for obtaining good records. Relatively quiet surroundings were also desirable, but absolute quiet was not essential. Accurate application of the microphone to the area in which the sounds were best heard was also of importance. Low amplification

11 Lewis Thomas. Illustrations of Heart Sound Records, Quarterly J Med 6 441 1912-1913

a pericardial friction rub was photographed. Fetal heart tones and the maternal souffle were satisfactorily photographed in a number of instances. In one case in which there was a tachycardia and a heart rate of 240 beats per minute, a satisfactory tracing was taken showing the first and second sounds about 1 cm apart.

Figures 2 to 7 are illustrations of some of the sound tracings taken with the electrostethograph. Figures 8

Fig. 9—Record with improved apparatus showing mitral stenosis.

to 10 were taken with an improved apparatus developed by Mr. Lockhart and the Cambridge Instrument Company in accordance with suggestions of Dr. H. B. Williams.¹²

The electrostethograph offers a satisfactory method of photographing heart sounds and appears to have certain advantages over the other types of recording devices. It can be operated wherever 110 volt alternating current is available. It is a small, compact unit that is entirely portable. Its operation is very simple, inexpensive and requires no unusual skill. The use of the viewing screen, on which the vibrations can be seen at the same time one is listening to and photographing the sounds, aids greatly in obtaining the best photographic records. Careful observation of the screen is also of aid in detecting certain abnormal

Fig. 10—Record with improved apparatus showing aortic stenosis with regurgitation.

sounds and locating their position in the cardiac cycle, this feature should be of particular aid in training the student. The photographic record of heart sounds is of distinct aid as a supplement to auscultatory observations as well as providing a permanent graphic record. In our experience with the electrostethograph there have been some oscillations of the base line for which we were unable to account, further study will be required to determine their significance.

ARTHRITIS

A COMPARISON OF THE CYSTINE CONTENT OF THE FINGERNAILS WITH THE SEDIMENTATION REACTION OF THE BLOOD

WILLIAM P. ARGY, M.D.

Associate Clinical Professor of Medicine, Georgetown University Medical School

WASHINGTON, D. C.

Sullivan and Hess,¹ using the Sullivan² cystine reaction, demonstrated that the cystine content of the fingernails in arthritis is, on the average, below normal and in many cases exceedingly low. This lowered cystine content of the fingernails was concluded to be an index of a toxic factor. Fischer³ and Westergren⁴ stated that the sedimentation reaction of the blood varies directly with the degree of intensity of the arthritic

process. Therefore an effort was made to compare the results of these two reactions in twenty-two unselected cases of this disease.

The cystine content of the fingernails was determined, in each instance, by Sullivan² and the results are expressed in the percentage of cystine in the total amount of nail clippings examined. The Cutler⁵ method was adopted for the estimation of the sedimentation reaction. The results of this procedure are expressed in millimeter readings, made at the end of one hour, as it has been proved by Fischer³ that additional readings offer no greater value.

Eight normal individuals were selected as controls, and the results of the examinations in each instance are recorded in table 1.

⁵ Cutler, J. W. The Practical Application of the Blood Sedimentation Test in General Medicine. *Am. J. M. Sc.* 133: 643-657 (May) 1932.

¹² Department of Physiology, Columbia University.

The presence of pain, limitation of motion or tenderness in the joints, associated with ankylosis, swelling or muscular rigidity or characteristic roentgen changes or a combination of these symptoms and signs was considered sufficient to make a diagnosis of arthritis. No cases were included which could possibly be tuberculous or syphilitic in nature, but no attempt was made to differentiate the cases selected into a more specific group than that of chronic nontuberculous arthritis.⁶ It is true that some of the cases could have been classified as rheumatoid, others as hypertrophic, atrophic or mixed types, but for the purpose intended this differentiation seemed to be unnecessary.

Table 2 is a record of the results of the examinations in each of the cases of arthritis.

Table 3 shows a comparison between the high, low and average readings of each reaction.

TABLE 3—Comparison Between Various Readings

Cystine Sedimentation	Low		High		Average	
	Normal	Arthritic	Normal	Arthritic	Normal	Arthritic
	10.38	7.41	13.02	12.20	11.08	9.66
	2	8	11	55	7.70	22.68

TABLE 4—Comparison by Decades

Distribution of Sedimentation Reaction	Average Percentage of the Cystine Content of the Fingernails	Number of Cases
0-10	10.85	4
10-20	10.36	6
20-30	0.33	6
30-50	8.51	6

It is evident from these tabulations that in only one instance was the cystine content of the fingernails above the average normal, but in this case the sedimentation reaction was close to the average normal. In this one instance (G S) the disease process had been arrested and the patient was suffering from residuals of a previously active process. In no instance was the sedimentation reaction below that of the average normal sedimentation reaction.

Further analysis reveals that when the results of the sedimentation reaction of each case are grouped into decades and the average readings of the cystine content of the fingernails of each group are compared with that of the other groups, these readings vary in general, in inverse proportion to the sedimentation reaction of the blood. Table 4 demonstrates this fact.

COMMENT

Although the number of cases studied is small, the results are so definite that it seems logical to conclude that, at least on the average, an inverse ratio between the cystine content of the fingernails and the sedimentation reaction of the blood does exist in arthritis. This is not true, however, in every instance, when the individual case is considered. These aberrations from the foregoing conclusions might be explained by the fact that the duration of the disease varied in each instance and the changes in the fingernails would not take place as rapidly as the changes in the sedimentation reaction of the blood. Therefore in the early stages of the disease or during a recurrent attack a normal cystine content of the fingernails with a high sedimentation reaction might be expected. Such variations, however, do not seem to influence the end result when the averages are considered.

The explanation of this phenomenon is problematic. Sullivan and Hess¹ believe that the decrease in the cystine content of the fingernails "implies an intoxication factor which draws on the sulphur complexes, as for example, glutathione, and thus diverts sulphur from its normal channels." It has also been suggested⁷ that an increase in the sedimentation reaction of the blood is also associated with an intoxication factor. If these theories are true, the results would indicate a toxic etiology in all the cases of arthritis that were studied. Furthermore, the fact that the variation is inversely proportional would suggest that this variation is indicative of the degree of toxicity.

Sullivan and Hess¹ also stated that this low cystine content of the fingernails in arthritis suggests a method of therapy with sulphur. Because of the inverse proportionate variation between the cystine content of the fingernails and the sedimentation reaction in arthritis it seems logical to conclude that an increase in the latter would presuppose a decrease in the former and thus sulphur therapy could be instituted without resorting to the more elaborate procedure of estimating the cystine content of the fingernails.

SUMMARY

Twenty-two cases of arthritis were studied, in order to compare the cystine content of the fingernails with the sedimentation reaction of the blood. It was found that these two reactions varied in inverse proportion. It has been suggested that such variations from normal could possibly indicate a toxic etiology in all the cases studied and that the control of this toxicity might be induced by the institution of sulphur therapy.

Clinical Notes, Suggestions and New Instruments

DIAGNOSTIC PROBLEM OF THE CAUSATION OF
DISPNEA REPORT OF A CASE
WITH AUTOPSY

LEWIS M. GAINES, M.D., ATLANTA, GA.

On Oct. 23, 1931, there came to my office for the first time a man, aged 48, whose chief complaints were shortness of breath and a feeling of abdominal distention. The patient was white, was married and his occupation was assistant manager of an office building.

The patient's story was that about six weeks previously, while getting out some old blue prints, which were covered with dust he inhaled a good deal of the dust and began to have paroxysms of severe coughing, which had continued more or less constantly. After enduring these coughing attacks for about a month he consulted a physician, who prescribed various forms of treatment but with little success. About October 13, while under treatment for the cough, he suddenly developed dyspnea and a feeling of abdominal distention particularly above the umbilicus. He found it difficult to breathe when lying down or when standing perfectly erect, his most comfortable position being a slightly stooped one or when sitting in a chair. His sleep was greatly broken by these complaints.

The cough had been dry throughout and was not so severe as formerly but still continued. There had been no nausea or vomiting and no abdominal complaints except the feeling of distention. The bowels had been regular. The patient's own explanation was that he was suffering from gas on his stomach, the pressure of which caused his shortness of breath. The patient explained that he had never been ill before in his life.

6. Fischer, A. G. T. Chronic Nontuberculous Arthritis. New York, Macmillan Company, 1929.

and that prior to the onset of his paroxysmal cough he did not have the slightest discomfort of any kind.

The dyspnea had been very distressing to the patient since its onset particularly on even such exertion as in walking from the street car on the level to the door of his home, a short distance away. The duties of his occupation have required going up steps and this has become impossible, owing to the extreme shortness of breath.

The patient was a large obese man, whose height was 6 feet 2 inches (188 cm) and weight 260 pounds (118 Kg). His face was rather pale but there was no evidence on inspection of either anemia or cyanosis. The pulse rate was 100 per minute, the blood pressure 126 systolic and 96 diastolic, the respirations 30, the temperature normal. Physical examination of the lungs revealed nothing abnormal. The heart did not appear to be enlarged, the sounds were rather distant though clear, and the rhythm was normal. The abdomen was pendulous and obese. There was a moderate amount of distention particularly above the umbilicus. Otherwise nothing could be found abnormal.

There was no edema in the extremities or elsewhere.

The patient was intelligent, cooperated and did not appear to be neurotic. He remarked apologetically that he hoped I would not think him a big baby for making so much complaint.

A specimen of urine examined at this time was completely negative.

Some simple remedies were prescribed pending further observation and examination.

The patient returned to the office, October 27, with his dyspnea somewhat more marked, and an account of sleepless nights. The pulse rate remained 100. An electrocardiogram was made, which showed an auricular rate of 100 and a ventricular rate the same. The PR interval was 0.19 second, the QRS interval 0.10 second, the RT interval 0.34 second. The rhythm was regular, the resistance 1,200 ohms. The electrocardiogram was made with the patient sitting. No therapy relative to the heart had been administered. In lead 1 QRS was low in amplitude, varied and there were marked slurring and notching. In lead 2 the amplitude of QRS was low, and there was slurring on the downward stroke. In lead 3 QRS was low in amplitude and there was marked slurring. With low electromotive force there was marked slurring and notching of QRS.

The clinical conclusion was that there had been myocardial damage.

Röntgen studies of the heart showed a small degree of dilatation of the aorta and apparent slight increase in the size of the heart but this was difficult to determine accurately because of marked abdominal distention.

Röntgen study of the lungs disclosed that the posterior mediastinum was apparently clear, though narrow in the center. The diaphragm appeared normal and the excursion was fairly good. There was marked increase of the hilus shadows particularly on the right. Shadow markings were general on both sides, with some mottling on the right, suggestive of small areas of consolidation.

Examination of the gastro-intestinal tract disclosed that a barium meal passed normally into the stomach. The gastric content was seen about 3 inches above the iliac crest, fairly movable at the pylorus. The anterior and posterior walls filled well. Peristalsis was slightly marked at the antrum. The cap did not fill smoothly. At the end of six hours the stomach was empty and the meal extended from the ileum to about midway of the descending colon, the greater portion of the meal having passed into the colon. A twenty-four hour study was not made.

After these studies it was felt that the only apparent explanation of the patient's disturbance was to be found in the myocardium. The patient was accordingly admitted to the Piedmont Hospital at once, October 27, and over a period of four days was given a total of 6 drachms (22.5 cc) of tincture of digitalis when with the appearance of nausea it was omitted. On admission to the hospital the pulse rate was 108, the respiration 30 and the blood pressure 138 systolic, 88 diastolic.

The blood examination revealed red blood cells, 4,560,000; white blood cells, 7,800; hemoglobin 90 per cent. The differential count revealed polymorphonuclear neutrophils, 61 per cent, polymorphonuclear eosinophils, 1 per cent, small mononuclears,

32 per cent, large mononuclears, 6 per cent. All blood cells were normal in size and shape, 200 cells were counted.

The urine, October 27, was normal except for a trace of sugar, acetone and diacetic acid. A few days later these traces had disappeared, except for a remaining trace of acetone and the appearance of a rare hyaline cast.

Both the Kahn and the Wassermann reactions on the blood were negative.

The patient remained in the hospital from October 27 until November 8. At no time was there any rise of temperature. His pulse rate varied from a low of 80 to a high of 110, the average being approximately 90. The respirations as recorded by the nurses varied from 20 to 40, the average being about 28. The frequency of the respirations, however, failed to give an adequate idea of the labored type of breathing. The patient was constantly gasping for breath and his sufferings in this respect became more and more painful to witness. His favorite position was sitting in a chair with his head resting on the bed in front of him. In such an attitude he was able to obtain short periods of comparative but not absolute comfort. Under the influence of morphine or pantopon together with amylal he was able to get as much as an hour at a time of sleep curled up on the bed on his right side with his pendulous abdomen supported by a pillow. What was extremely striking was the fact that, until near the end, cyanosis was conspicuous by its absence; in fact, the lips looked unusually red.

The abdominal distention continued despite satisfactory elimination, although at times temporarily relieved.

Those of us who watched the patient soon abandoned the idea that the state of his heart was responsible for the symptoms so severe and so agonizing.

The record of November 5 gives some indication of the state of the patient. After a restless night, broken by orthopnea and coughing, he could eat but little breakfast, after which there was nausea but no vomiting, and marked restlessness, nervousness and labored breathing. The greater part of the day was spent in a chair and in searching, though in vain, for such an attitude or posture as would give him some modicum of relief. Despite these sufferings the patient maintained efforts at cheerfulness, smiling wanly and expressing appreciation and gratitude for the efforts being made in his behalf. Such was the day.

Matters thus went from bad to worse until on November 8 his condition of distress was truly pathetic and he developed very definite evidence of heart failure. There was marked edema of the legs and diminution of urine with increase of pulse rate. Although large doses of morphine were administered, the patient was unable to lie down, was bathed in cold sweat, was constantly struggling for breath, and at intervals vomited. Consciousness, perhaps somewhat dulled by morphine, was retained almost to the last breath. Cyanosis appeared only during the last day or two of life. He finally died on the night of November 8.

In summary, a man aged 48, who had never been ill before, began to suffer with a paroxysmal dry cough about the middle of September and about five weeks later with severe dyspnea, which gradually and persistently increased in severity until his death and yet was unaccompanied by any cyanosis until there was evidence of terminal heart failure. The examinations as made give somewhat scanty and quite elusive clues of the cause of his profound disturbances.

Autopsy was performed, the body being opened in the usual manner. Panniculus was abundant, about 2 inches in thickness. When the abdomen was opened there was an outpouring of milky fluid. There was no evidence of peritonitis. The pericardium contained about 3 ounces of clear fluid. There was no evidence of pericarditis. The heart was about normal in size and there were no lesions of the endocardium or myocardium. Each pleural cavity was filled with clear fluid, there being fully 500 cc. in each cavity. The lungs were quite firm, containing little air and being almost bloodless on section. There seemed to be marked atelectasis of each lung. In the right upper lobe there were some areas of edema and bronchial pneumonia. There were no cavities. There was marked enlargement of all bronchial and mediastinal lymph nodes, which were soft and not scirrhous. The liver was about three fingerbreadths below the costal margin and was quite firm throughout on section. There was evidence of passive congestion but otherwise no

abnormal change. The spleen was normal in size and there was a small accessory spleen, on section there were no changes but passive congestion. There was a large nodular mass of lymph nodules up to 4 or 5 cm in diameter around and in the pancreas, inferior vena cava, duodenum and stomach. This was removed *en masse*. There were no tumor nodules in the intestine, the appendix being apparently normal and about 7 cm in length.

The stomach showed numerous nodules over the lesser curvature, rather hemorrhagic in appearance, varying in size up to about 5 mm in diameter, slightly projecting above the mucosa. This was more marked over the lesser curvature of the stomach. There was no pyloric obstruction. Both kidneys were normal in size and appearance; they were normal on section except for passive congestion. There were numerous large lymph nodules all up and down the anterior surface of the spine. There was a lymph nodule palpable in the right groin.

On microscopic examination, sections of the upper lobe of the left lung showed marked engorgement, the alveoli were filled with cellular exudate, round cells and polymorphonuclear and red cells. In areas the lung tissue was practically destroyed and filled with this cellular exudate.

Sections of the lower lobe of the left lung showed a somewhat similar condition, throughout the lung there were numerous oval areas made up of large cells, with large round nuclei containing several deeply stained chromatin granules. There was practically no stroma present in these areas. These cells were arranged in alveoli and they showed marked mucoid degeneration.

Sections of the perigastric glands showed complete destruction of normal tissue, which was replaced by large round cells and large granules. Mitoses were frequent. There was a tendency to alveolar arrangement, as in the lung and also marked mucoid degeneration.

Sections of the pancreas showed a somewhat similar involvement of glands about the pancreas.

Sections of the stomach showed marked infiltration of the mucosa throughout the gastric wall.

Sections of the kidney showed passive congestion, with some cloudy swelling of the tubular epithelium.

Sections of the heart muscle showed no definite pathologic changes.

Sections of the mesentery glands showed the same condition as the other glands.

Sections of the liver showed marked fatty infiltration and cloudy swelling but otherwise were negative.

Sections of the spleen showed marked passive congestion but were otherwise negative.

The pathologic diagnosis was (1) gelatinous adenocarcinoma of the stomach with metastases to the lungs and to the mediastinal mesenteric and retroperitoneal lymph glands, (2) chylous ascites, (3) pulmonary atelectasis with early bronchial pneumonia, bilateral hydrothorax, (4) passive congestion of the liver, spleen and kidneys.

COMMENT

The outstanding clinical feature of this case was the extremely urgent dyspnea without cyanosis until shortly before death together with a remarkable paucity of positive changes on examination. There were no symptoms whatever in the past history or during the illness pointing to gastric involvement. The roentgen studies of the lungs showed shadows suggestive of small areas of consolidation, but the appearance was so faint as to make uncertain definite interpretation. As the sequel shows, this finding was of importance.

One is impressed with the fact that a far advanced carcinoma of the stomach may occur together with extensive metastases without gastric symptoms, without impairment of nutrition and without anemia. The first evidences may be those dependent on metastatic involvement, as in this case. The diagnosis may not be established definitely until the autopsy. In cases of severe progressive dyspnea this possibility should be kept in mind when other demonstrable causes of dyspnea are absent.

CEVITAMIC ACID (ASCORBIC ACID) IN THE TREATMENT OF INFANTILE SCURVY

ARTHUR F ABT M D AND I M EPSTEIN M D CHICAGO

Not only is the isolation of a vitamin in crystalline form a matter of theoretical importance but such a discovery also has possibilities in practical clinical application. In 1928 Szent Györgyi¹ isolated a chemical which he thought was hexuronic acid and which he believed to be identical with vitamin C. Well controlled experiments on laboratory animals with this substance demonstrated that it protected against scurvy and cured this disease when experimentally produced. Zilva² in 1932 and Waugh and King³ in the same year published the results of such work. In 1933 the name of the isolated acid was changed to ascorbic acid, as its chemical formula became better known and it was found not to be a hexuronic acid. More recently the Council on Pharmacy and Chemistry of the American Medical Association has designated cevitic acid as the approved nonproprietary name for this substance.⁴

Merck and Company, who have supplied us with the acid both in tablet and in crystalline form, have designated their product as Cebione. It is a white or slightly yellow white, odorless crystalline powder, which melts at 189 to 192 C. and is freely soluble in water, soluble in alcohol, but practically insoluble in ether. It oxidizes on exposure to air and light. Its chemical formula is $C_6H_8O_6$. The formula for hexuronic acid, with which it was originally confused, is $C_6H_{10}O_8$. Cevitic acid may be isolated from various vegetable and animal sources such as cabbage, paprika, orange and lemon juice and adrenal cortex. The product with which Merck and Company have supplied us has been isolated from vegetable sources. It is said that 10 mg of crystalline cevitic acid corresponds to approximately 30 cc of the active vitamin C in fresh orange juice.

Cevitic acid was first used in human beings by Schultzer⁵ in 1933. He gave 40 mg of the crystalline acid by intravenous injection daily to an adult suffering with scurvy. As a result, the scurvy was cured. Four other reports have appeared in the literature of instances of human scurvy treated and cured with cevitic acid. Svendsgaard⁶ reported the cure of two cases (a 15 months old boy and a 10 months old girl baby) in which the crystalline vitamin was given by mouth. She gave 30 mg daily to each infant. Neumann⁷ reported the cure of one case (a 10 months old infant) by giving orally six tablets of Cebione (60 mg) daily. Brugsch⁸ reported the cure of a 13 months old infant by the oral administration of 30 mg of cevitic acid daily. Bauke⁹ reported the cure of an adult by the intravenous administration of 100 mg of crystalline Cebione daily.

Kramer¹⁰ in 1933 gave cevitic acid orally to a series of eighteen healthy infants. He gave it over periods of from one to six weeks. He concluded that premature infants tolerated 15 mg daily, new-born infants from 20 to 25 mg daily and healthy older nurslings from 25 to 50 mg. He reported no adverse results. On the basis of the chemical and laboratory animal work that had been done and the reported

instances in which human scurvy had been treated, we felt that we might properly use cevitamic acid in the treatment of infants with scurvy. We have three such cases to report. Merck and Company have supplied us with cevitamic acid in tablet form, which we have used in our cases. The tablets contain 10 mg of the acid compounded with lactose and are for oral use. They are best given dissolved in from 10 to 20 cc of water and are of a not unpleasant taste. For parenteral use the crystalline acid must be used after having been properly neutralized with sodium bicarbonate¹¹

REPORT OF CASES

Through the courtesy of Dr Edward W Beasley we were enabled to treat our first case, an 11 months old male infant who was admitted to the Provident Hospital Aug 22, 1934 with the clinical diagnosis of scurvy. The infant had had severe attacks of pylorospasm during the first few months of his life and had been on an evaporated milk water and sugar formula, with no orange juice. On admission the infant showed swelling and tenderness of the arms, legs and costochondral junctions of the ribs. Roentgenograms on admission showed the typical bony changes of scurvy including the raised periosteum with subperiosteal swellings. Attempts to administer the formula and orange juice to the infant during the first week of his stay in the hospital were most unsuccessful, owing to his vomiting everything offered by mouth. Saline and dextrose solution were given by hypodermoclysis, to combat dehydration. There was no improvement in the scurvy.

August 31, the treatment with cevitamic acid was begun by oral administration of one of the 10 mg Merck tablets three times daily. This oral dosage of 30 mg daily was continued for three weeks, and the tablets dissolved in from 20 to 30 cc of water, were successfully retained by the infant. Within forty-eight hours after the onset of treatment it was noted clinically that the infant exhibited a considerably lessened degree of tenderness and irritability. The course was complicated by superficial abscesses, which developed over the left humerus and right shoulder and which drained and healed slowly. One month from the onset of treatment the infant was discharged from the hospital with the scurvy cured and the secondary abscesses completely healed.

Roentgen examination, September 28, showed calcification of the subperiosteal hemorrhages. On admission the hemoglobin was 45 per cent, with 3.5 million red cells. September 20, the hemoglobin was 40 per cent, with 2 million red cells.

The other two cases were both treated at the Children's Memorial Hospital through the courtesy of Dr Joseph Brennemann. Irene P, aged 1 year, was referred to the hospital from the outpatient department with a diagnosis of scurvy, Oct. 24 1934. The essential physical changes were spongy, purple, bleeding gums about the erupted teeth, extreme tenderness of both legs, and some general swelling of the right leg. She had never had orange juice or tomato juice. Her entire diet prior to admission was a formula consisting of evaporated milk, water and Karo syrup and farina. The mother stated that until recently she had always had a boiled cow's milk formula. She had had small amounts of cod liver oil between the second and fifth months of life. The history of the present illness dated back two months, when the soreness of her gums was first noticed. For the last two weeks she had cried whenever she was touched.

The remainder of the history and physical examination was essentially negative. There was no anemia. The hospital diet was an evaporated milk, water and Mellin's food formula. Twenty mg of cevitamic acid was given orally each day for the first four days. After that 40 mg was given daily for ten days. There appeared to be less tenderness after twelve hours. There was definitely less tenderness and less swelling of the gums in twenty-four hours. After eight days the only remaining clinical evidence of the scurvy was the discoloration of the gums. Roentgen examination of the bones, October 25, was typical for scurvy. No subperiosteal hemorrhages could be identified.

The third patient, Stella R. aged 9 months was referred to the hospital from the outpatient clinic, Oct. 24 1934 with the

diagnosis of scurvy, aphthous stomatitis and laryngitis. The essential changes on admission were swollen, purplish spongy gums about the erupted teeth, hoarseness, and aphthous stomatitis. There was no localized tenderness. The stomatitis and hoarseness had been noticed six days previously. The other physical and laboratory examinations were negative except for hemoglobin 55 per cent red blood cells 3,200,000 and blood calcium 9.3 mg per hundred cubic centimeters. She had been on a diluted cow's milk formula since 1 month of age. One teaspoonful of orange juice a day had occasionally been given. No cod liver oil was used. She was given 20 mg of cevitamic acid orally each day for four days, then 40 mg daily for ten days. In two days the gums were less swollen and purple. Four days after admission there was practically no swelling of the gums. In eight days there was only slight discoloration. The hoarseness persisted throughout and was still present one month later. Roentgen examination of the long bones, October 25 was typical for scurvy. No subperiosteal hemorrhages were noted.

CEVITAMIC ACID CONTENT OF BLOOD SERUM

Besides being able to report the efficacy of cevitamic acid in the treatment of these three cases of infantile scurvy, we were enabled, in the last two cases to determine the cevitamic acid content of the blood serum, both before and after treatment. As far as we know, no such determinations have been previously reported in infantile or adult human scurvy.

The determinations of the cevitamic acid content of the blood serum were made by Dr Studeville in Dr Farmer's laboratory of Biological Chemistry at the Northwestern University Medical School. The method used for the test was that described by Tillman and based on the modifications of Harris and Ray.¹² In this method the cevitamic acid in the blood serum is deproteinized by means of trichloroacetic acid, and the protein free filtrate is titrated against an indicator, 2,6 dichlorophenol indophenol.

With this method, 4 cc. of blood from Irene P. was withdrawn, October 26 before treatment with cevitamic acid was begun, and the serum was found to contain 0.97 mg of the acid per hundred cubic centimeters. November 1, after six days of treatment the cevitamic acid content of her serum had increased to 2.01 mg and on November 8, after fourteen days, it was found to be 1.97 mg.

The blood of Stella R. was similarly examined. The initial examination, October 26, before treatment was started, showed her blood serum to contain 1.02 mg of cevitamic acid per hundred cubic centimeters. November 1, after six days of treatment, the blood serum value had risen to 2.03 mg and on November 8, fourteen days from the onset of treatment, the value was 2.06 mg.¹³

Attempts were also made to analyze the cevitamic acid content of specimens of urine from these two patients, but these examinations did not yield significant data.

COMMENT

Irrespective of the absolute values for the cevitamic acid content of the blood serum here presented, the marked increase in the serum following treatment must be considered significant. Comparing the analyses here given with the few serum values for apparently normal infants of approximately the same ages which we have been able to determine, it would appear that the cevitamic acid content of the blood serum in infants with acute scurvy is extremely low.

We conclude that, in the three cases presented, the oral administration of cevitamic acid seemed to cure infantile scurvy effectively. The dosage used was from 20 to 40 mg of cevitamic acid daily, given orally for from one to three weeks. We employed the 10 mg tablets made by Merck and Company and known by the trade name of "Cebione."

This method of treatment seems to be of especial value in those cases of infantile scurvy as in the first case here reported in which the infant failed to retain the orange juice offered in the way of treatment. In such cases in which severe

¹² Birch, T. W., Harris, L. J. and Ray, S. W. Microchemical Method for Determining Hexuronic Acid (Vitamin C) Content of Food stuffs. *Biochem. J.* 27: 590-593, 1933.

¹³ These results should be taken as comparative rather than as absolute values. Estimations which we have since made indicate that these figures are probably too high.

¹¹ Fisher, B. H. and Leake, C. D. The Parenteral Administration of Cevitamic Acid (Ascorbic Acid) Solutions. *J. A. M. A.* 103: 1556 (Nov. 17) 1934.

nausea and emesis make difficult or impossible the retention of the usual fruit and vegetable juices containing vitamin C, the smaller amounts of cevitamic acid in solution may be retained when given orally and effect a rapid cure.

The cevitamic acid content of the blood serum appears to be extremely low in infantile scurvy and is definitely increased after treatment with cevitamic acid.

If the chemical methods here mentioned prove sufficiently accurate for the determination of cevitamic acid in blood serum and urine it might be possible to demonstrate definitely a pre-scorbutic state in infants and children who manifest no signs or symptoms of active scurvy.

GLANDULAR PHYSIOLOGY AND THERAPY

THE LACTOGENIC FACTOR OF THE PITUITARY

OSCAR RIDDLE, PH.D.
COLD SPRING HARBOR, N. Y.

NOTE.—These articles and those in the previous 110 numbers of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues of THE JOURNAL.—ED

In 1928-1929 Stricker and Grüter demonstrated that a factor essential to lactogenesis is associated with the anterior pituitary. They did not identify or find other associations of the lactogenic principle, but crude saline and alkaline extracts were shown to initiate milk secretion in suitable rabbits, bitches, sows and cows—some of which were previously castrated. Their results were soon confirmed and further extended to rats, guinea-pigs and goats by Corner, Evans and Simpson, Nelson and Pfaffner, Turner and Gardner, Asdell and others. Also in these confirmatory studies—and in those of Riddle and Braucher on the crop-gland response—simple extracts containing mixtures of anterior pituitary principles were employed and the identity of the lactogenic factor remained unknown.

In 1932 Riddle, Bates and Dykshorn¹ succeeded in isolating the lactogenic factor in a degree of purity quite sufficient to demonstrate its distinction and separateness from the growth, gonad-stimulating and thyrotropic factors. At that time many investigators considered that the status of a true and separate hormone had been demonstrated for only the growth and sex factors, although a score of responses to pituitary extracts were known. For this third distinct (lactogenic) principle we proposed the name "prolactin".² Later, Gardner and Turner,³ using in part the method of preparation of the aforementioned workers, obtained the lactogenic factor fairly free from gonad-stimulating hormone. Their preparations of the lactogenic factor, called by them "galactin," were not tested for the thyrotropic factor, and reliance was put on a final addition of 0.4 per cent tricresol to destroy the growth hormone.

The various methods of preparing prolactin— all involve its initial acid or alkaline solution (aqueous, or 60 per cent ethanol), its iso-electric precipitation in an aqueous medium, and repeated washing of this precipitate. Catchpole and Lyons⁴ and Collip⁵ have also confirmed the isolation of prolactin by these methods. As now prepared, prolactin doubtless contains some inert protein, since about 0.1 mg. is required to give a detectable response (crop-gland). Salt free preparations at pH 8.0 withstand boiling for one hour, with relatively little loss of potency. It is completely destroyed by tryptic digestion⁶. In solution it is stable in the presence of tricresol and is completely soluble at pH 8.0. It can be obtained from the anterior pituitary only, beef glands yield larger amounts than do those of sheep or swine.

A knowledge of the various responses elicited by a hormone is necessary to a wise choice of a method for its bio-assay, and the "lactogenic" factor has proved to be more ancient than lactation. There are four known responses, or aspects of tissue response, to prolactin to consider for purposes of assay. These responses are lactation in mammals, growth of crop-glands in pigeons, broodiness in fowls and marked size diminution in active gonads of adult pigeons and fowl. The two last named responses are unsuitable for various reasons, but the crop-gland and lactation responses require consideration.

The crop-gland response in doves or pigeons was shown⁷ to be a reliable and practicable method of assay. Age and race of the test animal considerably affect the values found. For accurate assay five birds, either from one and a half to two months after hatching or nonincubating adult pigeons, are injected once daily for four days and killed ninety-six hours after the first injection. The weight of the two crop-glands after such dosage reveals the amount of new growth produced and thus the quantity of lactogenic factor injected. The "bird unit" was defined² as "the amount of prolactin which is equivalent to 1 mg. of (their) preparation No. 51, this being also the threshold dose per 150 grams body weight of immature doves and pigeons." The published data facilitate the calculation of this "unit" in any lactogenic preparation.

The induction of the lactation response in pseudo-pregnant rabbits has been used for a rough bio-assay (— to ++++) of the lactogenic factor, after various workers noted the unsuitability of rats and mice for this purpose. Gardner and Turner³ proposed such a "rabbit unit defined as that minimum amount of extract which injected during a period of seven days at daily intervals is required to induce a plus three (+++) or plus four (++++) response (appearance of dissected mammarys) in rabbits previously pseudopregnant for a period of twelve to sixteen days." Though satisfied with the crop-gland quantitative assay, Lyons and Catchpole⁸ report good qualitative tests from adult virgin guinea-pigs castrated during estrus and injected immediately.

There is no evidence that the development of mammary tissue is assisted in the slightest degree by the

lactogenic factor, and there is evidence⁹ that it has no such favoring effect. Some reports indicate that an unidentified pituitary factor favors mammary growth, but the lactogenic factor apparently acts on fully prepared mammary tissue solely to initiate and excite milk secretion. The mechanism by which prolactin is released, the reason for its impotence during pregnancy, the role of a uterine factor and of continued suckling or emptying of the milk ducts on the persistence of milk secretion, and still other topics in lactation physiology are very little known. Large amounts of prolactin—twice that found in adults—have been found in the pituitaries of fetal calves¹⁰. Similar amounts were obtained from the bull, steer and nonpregnant cow¹⁰.

A group of investigators at the University of Chicago have recently proposed the hypothesis, based on experimental observations, that the lactogenic factor of the pituitary is suppressed during pregnancy by estrogenic substance, normally produced in large amounts during this period. At the same time the estrogenic factor causes growth of the mammary glands. At parturition, with loss of the placenta, the level of estrogenic substance in the blood stream drops sharply, thus permitting the release of the lactogenic factor from the pituitary. The breasts, having been prepared in the meantime, then respond to this factor with secretion of milk. Riddle, Bates and Dykshorn showed that by first causing suitable growth of the mammary substrate, lactation may be produced even in males¹.

Kurzrok and his associates¹¹ treated twenty-nine women in whom lactation had failed to develop adequately by the sixth day post partum with from 75 to 400 units of prolactin. Within three to nine days the daily milk production increased by from 50 to 400 Gm in twenty-five of these cases. There were four failures, in three of which a total of 110 units or less was received. In eight additional women whose milk secretion was apparently normal, similar dosage probably induced no change. No adverse effect of clinical administration was observed. Further studies are needed. The dose of prolactin for subnormal human lactation was provisionally fixed at an initial 150 (bird) units, usually followed within twelve to twenty-four hours by 100 units.

CHROMATOPHOROTROPIC PRINCIPLE OF THE PARS INTERMEDIA OF THE PITUITARY

BERNHARD ZONDEK
JERUSALEM, PALESTINE

It has long been known that the hypophysis produces an active substance which exerts an influence on the chromatophores of cold-blooded animals. When one injects an extract of the posterior lobe of the pituitary into the lymph sac of a light colored frog (one previously exposed to light rays), the color of the skin becomes dark after a very brief interval. This change in color is due to the marked expansion of the melanophores². Swingle, as well as Allen, Atwell and Smith,

elicited a darkening of the skin in both normal and hypophysectomized tadpoles, by means of implantation of posterior pituitary tissue and by placing the animals into solutions of posterior pituitary extract. The expansion of melanophores can be elicited also by placing pieces of skin which have been cut from the animal into an extract of the posterior pituitary, the differing degrees of expansion have been used as a measure for quantitative standardization (Hogben and Winton, P. Trendelenburg, Loewe, Dietel, Jores). In employing this melanophore reaction in the isolated skin of frogs, it must be borne in mind that, whenever the solutions employed pass the neutral point and become acid, expansion occurs even in the absence of the specific principle, moreover, to obviate nonspecific reactions the solutions must remain isotonic. The reaction can be produced also by various nonspecific substances contained in organ extracts³ and by quinine curarine, choline, acetylcholine, caffeine, and various preservatives (Trendelenburg, Di Mattei, Ehrhardt).

Krohn and I⁴ employed the erythrophore-reaction in a certain fish to demonstrate the presence of chromatophore-stimulating hormone. When one injects an extract of posterior pituitary into a certain minnow (*Phoxinus laevis*), which is from 7 to 9 cm long, a characteristic red coloration appears within half an hour at the point of attachment of the thoracic, abdominal and anal fins. The appearance of this red coloration is not dependent on exogenous factors, such as light, nor on the pH of the injected solution, it can be produced only by the chromatophore-expanding hormone and is, therefore, "hormone specific". That quantity of hormone which produces a deep red coloration of from 4 to 9 square millimeters at the point of attachment of the fin is designated as one Phoxinus unit⁴.

All authors agree that the chromatophorotropic substance is produced in the intermediate lobe of the hypophysis (Swingle, Hogben and Winton, Allen, Atwell, Houssay and Unger, Trendelenburg, van Dyke). This is also evident in a curious phenomenon described by Bayer,⁵ who observed an individual frog (*Rana esculenta*) that was conspicuous by reason of its unusually light color, this persisted even when the animal was kept in the dark. Histologic examination showed that, in this animal, a parasite had destroyed the pars intermedia of the pituitary while the other portions of the gland were completely unaffected.

We analyzed the various lobes of pituitary glands of cattle and found that their hormone content was as follows

- 1 Pars intermedia, 80,000 Phoxinus units per gram of tissue
- 2 Posterior lobe, 11,904 Phoxinus units per gram of tissue.
- 3 Anterior lobe 2,857 Phoxinus units per gram of tissue

We call the hormone "intermedin"

Intermedin occurs in cold blooded as well as in warm blooded animals. In the pituitary gland of the minnow, we found 7 Phoxinus units, of the frog, 10 Phoxinus units, of the chicken, 75 Phoxinus units, of the rabbit, 200-300 Phoxinus units, of the sheep, 2,500 Phoxinus units, of cattle, 5,000-6,000 Phoxinus units, of the monkey (*Macacus rhesus*), 1,000 Phoxinus units and

of man, 4,000-7,000 Phoxinus units. Analysis of the hypophysis of human beings who died of various diseases showed no marked variation of intermedin content. In three pituitaries from Negroes, we found the same intermedin content as occurs in the glands of white men.

The hormone leaves the hypophysis by the path of the pituitary stalk. According to our investigations, it is demonstrable only in the walls of the third ventricle, where the vegetative centers are located, and nowhere else. In contradiction to this, Krogh and McLean,⁶ using the melanophore reaction, demonstrated the hormone in small quantities in the blood as well. Jores⁷ reports a content of from 0.5 to 1.5 units per liter of plasma, estimated on the basis of alkaline-Vogtlin standard.

In contrast to the changes in the case of the gonadotropic factors, we found no change in quantities of chromatophore-expanding hormone in pregnancy.

The question arises: Is the chromatophore-stimulating substance an independent hormone? Kamm, Aldrich, Grote, Rowe and Bugbee succeeded, as is well known, in the separation of the oxytocic factor ("Pitocin") and the pressor principle ("Pitressin").⁸ They believe that the melanophore-stimulating substance which is present in varying amounts in Pitressin is possibly a "derived hormone." They emphasize, however, that to date there is no proof of the presence of more than two hormones (i.e., Pitocin and Pitressin).

We are of the opinion that the chromatophorotropic substance must be a specific hormone, for the following reasons:

1. Intermedin is lacking in the suboccipital liquor, while Pitocin and Pitressin are present.

2. Intermedin can be demonstrated in the pituitary colloid, while Pitocin and Pitressin are absent (Cushing and Goetsch). Thus, intermedin occurs independently in the organism, i.e., it is present without the oxytocic and pressor factors.

3. The quantitative proportion of intermedin to the oxytocic and pressor factors is quite different in the different lobes of the pituitary.

Proof that the chromatophore-expanding substance is an independent hormone was finally brought when we succeeded in isolating intermedin. Lack of space prevents mention of further details. Mention need be made only of a few characteristics of the hormone. Intermedin is thermostable at boiling temperature, it is resistant to cold, it is very susceptible to the action of proteolytic ferments, and it is quickly inactivated by irradiation with ultraviolet rays. The hormone is insoluble in ether, acetone and acetic esters, and it is soluble up to 5 per cent in benzene and in chloroform. The hormone's solubility in alcohol increases with the purity of the preparation. Intermedin is easily adsorbed. Its susceptibility to the action of mineral acids is approximately parallel to that of Pitocin and Pitressin, while it is less susceptible to the action of alkalis. These differences were already indicated by the investigations of Hogben¹ and Gordon. We were able to produce intermedin as a fine, amorphous, white powder with a dry weight of 1 microgram (0.000001 Gm.) per Phoxinus unit.

In cold blooded animals (frogs, fishes), intermedin elicits the expansion of the chromatophores. After intravenous injections of large quantities of intermedin into warm blooded animals, we were able to recover only small traces (0.14 per cent) in the blood, after from one to three hours, but none could be demonstrated in the organs or in the urine.

Intermedin exerts no influence on the basal metabolic rate, on the blood pressure, or on the glycogen and fat contents of the liver. On the other hand, it is possible that it reduces the epinephrine content of the adrenals, although the variations are insignificant. It is worthy of mention that Jores attributes an importance to intermedin in the adaptation of the optic organs to darkness, in man as well as in animals.

It is now necessary to consider the question of the action of intermedin on water metabolism, and of its identity with the antidiuretic factor.

Marion B. Sulzberger of New York,⁹ employing an intermedin preparation obtained from me, achieved striking success in the treatment of two cases of diabetes insipidus. Both the fluid intake and the output were greatly reduced. A confirmatory observation was made by Harald Bark of Stockholm, who observed reduction of urine output from 5.0 to 1.5 liters, and an increase of specific gravity from 1.005 to 1.020.

Subsequent extensive investigations, which were undertaken at my suggestion in the Pharmacological Laboratory of Hoechst, I. G. Farbenindustrie, showed that fundamental differences exist between the action of intermedin and that of Pitressin in their action on water metabolism. The characteristic action of Pitressin consists in reduction of fluid output, combined with both relative and absolute increase of sodium chloride excretion. Intermedin, on the other hand, while it definitely influences fluid output, does not affect salt excretion, the exact manner of its action is as yet unknown.

It seems to me that these results suggest the possibility that intermedin may act only in certain types of diabetes insipidus and that, perhaps in this way, a differential diagnostic criterion may be formed which will help to distinguish between different forms of this disease.

The melanophore-stimulating hormone and the erythrocyte-stimulating hormone may be two different substances, or, perhaps, different forms (alkaline, acid) of the same hormone (Jores).¹⁰

9 Sulzberger, M. B. The Pituitary Hormone Intermedin. *J. A. M. A.* 100: 1928 (June 17) 1933.

10 Translator's Note: Further clinical experience with intermedin in the treatment of diabetes insipidus permits me to state that the antidiuretic effect of various intermedin preparations seems to be independent of and not to run parallel with their Phoxinus erythrocyte-expanding potency. It is therefore evident that one cannot employ the Phoxinus reaction to standardize a preparation for its antidiuretic effect in diabetes insipidus.

Furthermore, according to frog melanophore standardizations which were kindly carried out for me by Dr. Oliver S. Kamm, an intermedin preparation which had assayed high in Phoxinus erythrocyte-expanding activity was very low in frog melanophore stimulating action. And conversely, Phoxinus erythrocyte standardization kindly performed for me by Dr. Charles Spark at the Montefiore Hospital of New York City showed that a certain pituitary preparation which was high in frog melanophore stimulating activity had practically no demonstrable action on the Phoxinus erythrocyte. This potent frog melanophore-stimulating preparation (which Doctor Kamm was kind enough to send me) differed from intermedin in that it had no effect in controlling diuretics in my cases of diabetes insipidus.

These unpublished observations may be considered as supporting the suggestion contained in Dr. Zondek's last paragraph.

Moreover, it seems to me more than probable that there are at least three different principles to be considered:

1. A Phoxinus erythrocyte-expanding principle (present in intermedin).

2. A frog melanophore-expanding principle, and

3. An antidiuretic principle active in diabetes insipidus in man (present in intermedin in varying quantity).

It remains undecided whether each principle is actually an independent hormone or whether these divergent effects are due to so-called derived substances.

CHICAGO

NOTE.—In their elaboration these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics Dr Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed

THERAPY OF ACNE AND ACNE ROSACEA OUTLINE BY THEODORE CORNBLEET, M.D.

ACNE

Local and systemic measures are used

Systemic Treatment — 1 Such predisposing disturbances as constipation and other gastro-intestinal abnormalities, or pelvic and menstrual derangements that may be present should be corrected. One should seek out and remove foci of infection.

2 Alcohol should be prohibited and tobacco, coffee and tea reduced to a minimum. Foods rich in sugar and fats and oils, particularly the vegetable fats, should be taken sparingly. Articles that frequently produce distress should be avoided. In this group may be included pickles, rich cheeses, pork and sausages. Those things which may cause congestion of the face, such as very hot soups or highly seasoned foods, should be excluded. The diet however, should not be so restricted or one sided as to fail to maintain good nutrition.

3 Tonics and alteratives may be employed as indicated e. g., Solution of Potassium Arsenite (from 0.5 to 1 cc three times a day) or, if there is hypochromic anemia, Ferrous Carbonate (0.3 Gm three times a day) with Strychnine Nitrate (1 mg) possibly, unless there is exaggerated reflex excitability. Diluted Hydrochloric Acid (1 cc in water after meals) may be of advantage in cases of hypochlorhydria. Yeast and liver are recommended by some, the laxative action of the former, and the hematonic action of the latter possibly determining the choice. Quinine sulphate 0.2 Gm three times a day and adrenal gland substance 0.25 Gm three times a day are much used.

4 Foreign protein and vaccines occasionally give brilliant results but often are failures. Some recommend autogenous vaccines, while others claim as much for stock vaccines. A combination vaccine of acne bacillus, staphylococcus and the colon bacillus ("mixed acne vaccine") is probably as good as any. The dosages should be built up to produce and maintain a local reaction. The intervals of administration, possibly four to seven days, should be so spaced as to get a rhythm of reaction and subsidence.

5 Some drugs, such as iodides and bromides, have a tendency to produce acne-like lesions or to aggravate an existing acne. To those with acne these drugs, including iodized salt, should not be given, or if such an eruption appears during their administration, they should be promptly withdrawn and the amount of sodium chloride in the diet increased.

Local Treatment — 1 Cleanliness. The ordinary use of soap and water is sufficient. Under the mistaken notion that blackheads are due to uncleanness, fanatic measures are sometimes employed to remove imagined dirt. Generally acne is associated with a skin that has enough oil. It is therefore generally unnecessary to use creams. Cleansing tissue and the multitude of beauty creams are not only a waste of money in this condition but often positively harmful. Indeed, the deceiving propaganda with which they are foisted on the gullible should be prohibited. Face powders containing heavy metals must be excluded.

2 Drainage. Comedones should be removed by an instrument for that purpose and not be squeezed. The skin should first be thoroughly softened by hot water soaks for from half an hour to a whole hour. It is best for the physician himself to extract the comedones and at the same time to have him carefully open pustules with a narrow bladed bistoury.

3 Keratolytics. These favor drainage by hastening the maturing of pustules and by producing epidermal exfoliation at the neck of the follicles in addition to producing a curative hyperemia. Much used are

(a) 'Lotio Alba' (prescription 1), which might be prescribed in double or even triple the strength in accordance with the reactivity of the skin. It is applied before retiring and permitted to dry on.

PRESCRIPTION 1—'Lotio Alba'

R	Zinc sulphate	5.00 Gm
	Sulphurated potassa	5.00 Gm
	Rose water to make	100.00 cc
M	Label: Shake well and apply two or three times a day after steaming face	

(b) Solution of Sulphurated Lime (Vlemmink's lotion), which must be diluted from eight to sixteen times with hot water, used for an hour on a gauze compress. A mild irritation manifesting itself after several days by hyperemia should be aimed at as the result of treatment with either preparation, and the concentration of the applications should be increased if this is not attained. After mild scaling and erythema appears, treatment is suspended and a soothing application such as Calamine Lotion or Calamine Liniment may be employed, the latter being used if the former is too "drying." Recovery from this irritation is followed by a resumption of the original lotion to induce mild irritation again.

(c) Peeling Paste, such as Lassar's Peeling Paste (in the National Formulary under the title of Betanaphthol Paste, containing Betanaphthal 10 per cent, Precipitated Sulphur 50 per cent, made into a paste by means of equal parts of petrolatum and soft soap). This is a still more powerful discutient appeal to the skin, of special value in indurated acne, and suitable only for individuals with an especially sluggish skin.

PRESCRIPTION 2—Resorcinol (1 Per Cent) Paste

R	Resorcinol	0.35 Gm
	Zinc oxide	
	Starch	of each 5.00 Gm
	Petrolatum	15.00 Gm
M	Label: Apply at bedtime	

It is applied liberally and washed off after fifteen thirty or forty-five minutes. As they are difficult to control, it is not advisable to put peeling pastes into the patients' hands. Their application must be carefully timed by the physician.

The different degrees of irritative effect secured by these three different methods of applying must be care-

fully adjusted to the requirements of the case. One should always start with the milder preparation and work up to the stronger only after the milder has proved not to be irritating.

4 **Rubefacients**—In cases in which keratolytic action is not required, the curative hyperemia may be induced most advantageously perhaps by very mild applications of resorcinol which, being colorless, is especially suitable for the face.

(a) **Resorcinol Pastes** are official in the National Formulary in two forms: the Mild Resorcinol Paste (containing 10 per cent) and the Strong Resorcinol Paste (containing 20 per cent). The latter is strong enough to be used as a peeling paste. Both are too strong to be advisable as an initial application to a skin whose irritability is unknown. Hence it is well to start, e. g. with 1 per cent of resorcinol (prescription 2) and gradually increase the strength until the desired degree of peeling effect has been secured.

PRESCRIPTION 3—Sulphur (2 Per Cent) Paste

R	Precipitated sulphur	0.50 Gm.
	Zinc oxide	
	Starch	of each 5.00 Gm.
	Petrolatum	15.00 Gm.
M	Label: Apply at bedtime	

(b) **Sulphur** is especially indicated by simultaneous existence of seborrhea. It is again best used in the form of a paste (prescription 3), starting possibly with 2 per cent strength and increasing to 5 and 10 per cent. Dark discoloration of the openings of the sebaceous glands and of the comedones is one of the unfavorable effects of sulphur in certain individuals that may make it impossible for them to use this agent.

All of these salves are, of course, suitable for application only at bedtime. During the day one might prescribe the use of sulphur added to the patient's favorite face powder (prescription 4).

PRESCRIPTION 4—Face Powder with Sulphur

R	Precipitated sulphur	3.00 Gm.
	Face powder	30.00 Gm.
M	Label: Apply to face during the day	

4 **Irradiation** (a) Roentgen therapy is the most valuable single agent to be used. It is helpful in a majority of cases but fails in some. The greatest care should be used in calculating dosage and none but an experienced operator should employ this measure. Fractions of an erythema dose (e. g., 75 roentgens of unfiltered rays weekly, eyes, ears, eyebrows, scalp and other hair, and the thyroid carefully shielded) are used at regular intervals. This should not be carried out indefinitely, but the total dosage limited. A visible erythematous reaction in the skin must never occur, and the development of skin atrophy must ever be kept in mind, most especially when one is tempted to employ roentgenization in recurrences. During the use of roentgen therapy no applications that are irritating, even mildly, may be employed. (b) In some patients who are resistant to γ -rays, ultraviolet rays are sometimes effective. These are used to the point of achieving a mild erythema and scaling. The dosage is increased according to tolerance to maintain this reaction. The applications are generally given at weekly intervals or as soon as the reaction subsides. Ultraviolet rays are also used to improve the appearance of the pits and scars from acne temporarily. To do this a severe enough reaction must be obtained to ensure thorough exfoliation.

ACNE ROSACEA

For the most part, the treatment of acne rosacea is the same as for acne itself. The earlier the treatment commences, the better are the results obtained. When the stage of permanent congestion is reached, it is difficult to ameliorate.

General Measures—These are of even greater importance in acne rosacea than in acne vulgaris.

1 Both the gastro-intestinal and genital tracts influence acne rosacea. Care of digestive disturbances and constipation is important. Dietary control as suggested in acne is necessary here, only more so. Foods that dilate the blood vessels of the skin should be avoided. These include steaming hot ones and those with many condiments. Alcohol and coffee must be excluded. Menstrual disorders and pelvic derangements should be corrected. Focal infections are searched for and removed.

2 If possible, occupations that subject the face to any irritations should be given up or modified. Exposure to rough weather and excessive heat is to be avoided.

Local Measures—1 **Keratolytic Lotions**. These are nearly always a part of the treatment. The two most important are, as with acne, the "lotio alba" and "Vlemmick's solution." By a judicious use of them, of the right concentrations to obtain and continue an almost imperceptible exfoliation, the congestion and pustules can in a large measure be removed. The local application of extremes of heat and cold should be carefully avoided in the treatment of acne rosacea.

2 **Irradiation** (a) Roentgen therapy is effective and is carried out in repeated fractional doses. As in acne, care should be exercised to give a small enough dose so as not to obtain an erythematous reaction at any time or to produce skin atrophy as an end result.

(b) **Ultraviolet rays** by means of the water-cooled quartz lamp are useful at times.

3 **Cryotherapy**. Carbon dioxide snow (dry ice) shaped into pencils not over 1 cm. in diameter may be applied with a fair degree of pressure for not more than one second at a spot. If this causes no reaction or improvement, the time of application may be gradually increased but always to a point short of an excessive reaction.

4 **Electrolysis** can be used to advantage to remove the dilated capillaries and venules, which often are associated with or remain after the general congestion is relieved. The needle, which is made the negative pole, is inserted into the venule and a current of from 1 to 2 milliamperes is applied until the area turns white.

PRESCRIPTION 5—Paraffin-Petrolatum Cerate

R	Paraffin	10.0
	Petrolatum	20.0
M	Label: Spread aseptically on sterile gauze and apply to raw surface	

5 **Surgery** to remove the redundant tissue of the nose in the stage called rhinophyma can accomplish a great deal cosmetically. A sharp scalpel or razor blade is used to pare away enough tissue to leave the original shape of the nose. Care must be taken not to cut or injure the cartilage. To guard against this, one should insert a finger into the nose to act as a director. Surgical diathermy may be used. The small excrescences can be conveniently coagulated and the larger ones

removed with the cutting current. The entire procedure may be carried out at one time or smaller areas treated at different sittings. A 2 per cent solution of procaine hydrochloride with epinephrine serves as an adequate local anesthetic. Hemorrhage is controlled easily with hot gauze compresses changed every two to four hours the first day and several times a day after that. The raw area may be treated as a burn and covered with paraffin-petrolatum cerate (prescription 5) gauze changed frequently enough to prevent the formation of hard crusts. Epithelization takes place readily from the islands remaining in the follicles and complete healing is a matter of from three to five weeks. The results are excellent.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

ALURATE—Allylisopropylbarbituric acid—Allylisopropylmalonyl urea — $(C_2H_5)(C_2H_5)CCONHCONHCO$ Alurate

differs from barbital (diethylbarbituric acid) in that both of the ethyl groups of the latter are replaced, one by an allyl group and the other by an isopropyl group.

Actions and Uses—The actions and uses of alurate are essentially similar to those of barbital, but alurate is more active than barbital and is used in correspondingly smaller doses. Fractional doses are used as a sedative and larger doses as a hypnotic. Therapeutic doses act on the higher centers of the brain and are claimed not to exert any apparent injurious effect on the heart, circulation or kidneys.

Dosage—For mild cases of insomnia, 0.065 Gm (1 grain) may be administered at bedtime. In obstinate cases, 0.13 Gm (2 grains) may be given.

Manufactured by Hoffmann-La Roche, Inc., Nutley, N. J. U. S. patent 1,444,802 (Feb. 13, 1923, expires 1940). U. S. trademark 230,059.

Alurate Tablets 1 gr

Elixir Alurate—Each fluidrachm contains alurate $\frac{1}{2}$ grain (approximately 0.9 Gm per hundred cubic centimeters) in a palatable elixir containing alcohol 20 per cent.

Alurate occurs as a fine white, odorless crystalline powder with a slightly bitter taste, completely soluble in alcohol, chloroform and ether, very slightly soluble in cold water, insoluble in the paraffin hydrocarbons. A saturated aqueous solution is acid to litmus paper. Alurate melts at 138 to 142°C.

Place about 0.3 Gm of alurate in a glass stoppered cylinder, add a mixture of 1 cc of normal sodium hydroxide solution and 5 cc of water, shake the contents for one minute, filter through paper and divide into two portions. To one portion add 1 cc of mercuric chloride solution, a white precipitate results, soluble in an excess of ammonia water. To the other portion add 5 cc of silver nitrate solution, a white precipitate results, soluble in an excess of ammonia water. Boil about 0.5 Gm of alurate with 5 cc of a 25 per cent sodium hydroxide solution, it is decomposed with the evolution of ammonia. Dissolve about 0.1 Gm of alurate in 1 cc of sulphuric acid, not more than a slight yellow color results. Place about 1 Gm of alurate in a 25 cc glass stoppered cylinder, add 10 cc of water, shake the mixture for one minute, filter through paper and divide into two portions. To one portion add 1 cc of acetic acid and 0.5 cc of a saturated bromine water, an immediate discoloration occurs. To the other portion add 0.1 cc of tenth-normal potassium permanganate solution, a yellow color appears immediately, turning to brown.

Boil about 0.5 Gm of alurate with 50 cc of water for two minutes, no odor develops, cool and filter, separate portions of 10 cc each of the filtrate, yield no opalescence with 1 cc of diluted nitric acid and 1 cc of silver nitrate solution (chloride), no turbidity with 1 cc of diluted nitric acid and 1 cc of barium nitrate solution (sulphate), no coloration or precipitation on saturation with hydrogen sulphide (salts of heavy metals). Incinerate about 1 Gm of alurate accurately weighed, there is not more than 0.1 per cent residue. Dissolve about 0.5 Gm of alurate accurately weighed in 25 cc of previously neutralized alcohol, dilute with an equal volume of water, previously boiled to remove carbon dioxide and titrate with tenth-normal sodium hydroxide solution, using thymolphthalein as an indicator, the amount of tenth-normal sodium hydroxide solution consumed corresponds to not less than 98.5 per cent nor more than 101.5 per cent allylisopropylbarbituric acid.

SODIUM ALURATE—Sodium allylisopropyl barbiturate
— $Na(C_2H_5)(C_2H_5)CCONHCO NCO$ —The monosodium salt

of allyl isopropyl barbituric acid. Sodium alurate differs from soluble barbital U. S. P. (sodium diethylbarbiturate), in that both of the ethyl groups of the latter are replaced, one by an allyl group and the other by an isopropyl group.

Actions and Uses—The same as those for alurate. The soluble sodium salt is intended for oral or rectal administration, particularly as preanesthesia medication. Sodium alurate may also be used in other cases in which large individual doses are required.

Dosage—The average preoperative dose is 1 grain for each 15 pounds of body weight (10 mg per kilogram). One third of the calculated dose is given ten or twelve hours prior to operation, (usually the evening before), the remainder, two hours before operation. Experience is necessary in the use of these large dosages, as the amount of the drug must be adjusted to the individual patient in order to avoid undesirable reactions.

Manufactured by Hoffmann-La Roche, Inc., Nutley, N. J. U. S. patent 1,444,802 (Feb. 13, 1923, expires 1940). U. S. trademark 230,059.

Capsules Sodium Alurate $\frac{3}{4}$ grains—The content of each capsule is equivalent in potency to approximately 3 grains of alurate.

Sodium alurate is a white microcrystalline, hygroscopic, odorless powder with a slightly bitter taste, very soluble in water, very slightly soluble in alcohol, practically insoluble in ether. An aqueous solution of sodium alurate is alkaline to litmus.

Dissolve about 0.5 Gm of sodium alurate in 100 cc of water, add an excess of diluted hydrochloric acid, collect the resultant allyl isopropyl barbituric acid on a filter, wash and dry at 90°C, it melts at 139 to 140°C. Incinerate about 1 Gm of sodium alurate, the residue responds to tests for sodium carbonate. Boil about 0.5 Gm of sodium alurate with 5 cc of a 25 per cent sodium hydroxide solution, it is decomposed with the evolution of ammonia. Dissolve about 0.3 Gm of sodium alurate in 10 cc of water and divide into two portions. To one portion add 1 cc of mercuric chloride solution, a white precipitate results, soluble in an excess of ammonia water. To the other portion add 5 cc of silver nitrate solution, a white precipitate results, soluble in an excess of ammonia water.

Dissolve about 0.5 Gm of sodium alurate in 50 cc of water, add 5 cc of diluted nitric acid and filter through paper, separate portions of 10 cc each of the filtrate, yield no opalescence on the addition of 1 cc of silver nitrate solution (chloride), no turbidity on the addition of 1 cc of barium nitrate solution (sulphate). To about 0.2 Gm of sodium alurate in 25 cc of water, add 1 cc of diluted hydrochloric acid, filter through paper, the filtrate yields no coloration or precipitation on saturation with hydrogen sulphide (salts of heavy metals). Add about 1 Gm of sodium alurate to 1 cc of sulphuric acid, the solution is colorless (readily carbonizable substances). Transfer about 1 Gm of sodium alurate accurately weighed to a glass stoppered cylinder, add 50 cc of anhydrous ether, stopper and shake for ten minutes, decant the supernatant liquid through filter paper and repeat twice using 25 cc and 15 cc portions, respectively of ether, utilizing the same filter, evaporate the combined filtrates to dryness in a tared beaker and dry to constant weight at 90°C, the residue does not exceed 0.2 per cent (uncombined allylisopropyl barbituric acid).

Dry about 1 Gm of sodium alurate accurately weighed at 90°C for forty-eight hours, the loss in weight should not be less than 4.5 per cent nor more than 7.5 per cent. Transfer about 0.5 Gm of sodium alurate accurately weighed to a suitable Squibb separatory funnel, add 50 cc of water followed by addition of 10 cc of diluted hydrochloric acid, extract with eight successive portions of ether of 25 cc each, evaporate the combined ethereal extractions to dryness in a stream of warm air and dry to constant weight at 90°C, the amount of allylisopropyl barbituric acid corresponds to not less than 90 per cent nor more than 91 per cent calculated to the dried substance. Transfer the acidulated aqueous portion from the foregoing immiscible solvent extraction to a tared platinum dish and evaporate to dryness on a steam bath, to the residue obtained add 5 cc of sulphuric acid, heat cautiously until the excess of sulphuric acid has been volatilized, repeat twice using portions of 1 cc each of sulphuric acid, each time add about 0.5 Gm of ammonium carbonate, ignite to constant weight and weigh as sodium sulphate, the percentage of sodium corresponds to not less than 9 per cent nor more than 10 per cent when calculated to the dried substance.

DIOTHANE (See THE JOURNAL, Dec 8, 1934, p 1777)

The following additional dosage form has been accepted

Diothane Ointment 1% in Ophthalmic Tube—Collapsible tubes containing an aqueous solution of diothane 1 per cent in an oxycholesterin base.

NEO-SYNEPHRIN HYDROCHLORIDE (See THE JOURNAL, June 16, 1934, p 2024)

The following additional dosage form has been accepted

Neo-Synephrin Hydrochloride Jelly—Neo-synephrin hydrochloride 0.5 per cent incorporated in a jelly like bland base composed of tragacanth, chondrus, glycerin and water. Sodium benzoate 0.5 per cent is present as preservative. The product is supplied in collapsible tube containers.

DILAUDID (See THE JOURNAL, June 16, 1934, p 2024, Dec 1, 1934, p 1708)

The following dosage form has been accepted

Dilaudid Compounding Tablets $\frac{1}{4}$ Grain—Each tablet contains dilaudid one-half grain. These tablets each many times the average dose are for use in compounding only.

RADIOLOGIC SERVICE IN THE UNITED STATES

REPORT BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The names of 1,286 physicians specializing in radiology are included in the fifth publication of the Council's list. Up to the present time this number has been found to qualify according to the 'Essentials' prepared by radiologists and passed on by the House of Delegates of the American Medical Association. A number of applications are now pending and new applications are considered as they are submitted.

The type of service rendered is given opposite the name 'Radiology' under "Type of Service" always includes short wave therapy, also known as 'deep therapy.' The asterisk (*) on Roentgenology indicates that short wave therapy is included.

A list of physicians specializing in radiology in government service will be found on page 651.

The work of the Council in designating those qualified in radiology has been wholesome in its effects. Physicians generally have been encouraged to refer their work to medical graduates recognized as specialists in this field. There is abundant evidence that independent lay practitioners have been effectively discouraged through the Council's efforts.

The Essentials have been printed in former issues of the Radiologic Number of THE JOURNAL. The exact method of preparing the list may be referred to in THE JOURNAL, March 19, 1932, page 984. Application blanks are secured from the office of the Council.

SATURDAY, FEBRUARY 23, 1935

HOUSE OF DELEGATES ADOPTS POLICIES ON SICKNESS CARE

The special session of the House of Delegates called at the request of the Board of Trustees met in Chicago, February 15 and 16. As will be apparent from the minutes of the House, to be published in THE JOURNAL next week, the session opened with a statement by the Board of Trustees, giving the record of the Association in relationship to this subject and propounding to the House of Delegates six questions of moment. After much general discussion, the speaker of the House of Delegates referred the entire discussion on these six questions to a reference committee, which then brought in a report to the House. This report was unanimously adopted by the House after suitable correction and amendment. It is important that every member of the American Medical Association read carefully this statement of policies and support it to the utmost with his patients and with representatives in state legislatures and in the federal government. The report of the reference committee opens with a preamble stating in general the point of view of the American Medical Association and its right to speak for the medical profession on this subject.

The American Medical Association, embracing in its membership some 100,000 of the physicians of the United States, is by far the largest medical organization in this country. The House of Delegates would point out that the American Medical Association is the only medical organization open to all reputable physicians and established on truly democratic principles, and that this House of Delegates, as constituted, is the only body truly representative of the medical profession.

The House of Delegates commends the Board of Trustees and the officers of the Association for their efforts in presenting correctly, maintaining and promoting the policies and principles heretofore established by this body.

The primary considerations of the physicians constituting the American Medical Association are the welfare of the people, the preservation of their health and their care in sickness, the advancement of medical science, the improvement of medical care, and the provision of adequate medical service to all the people. These physicians are the only body in the United States qualified by experience and training to guide and suitably control plans for the provision of medical care. The fact that the quality of medical service to the people of the United States today is better than that of any other country in the world is evidence of the extent to which the American medical profession has fulfilled its obligations.

The first question propounded by the Board of Trustees to the House of Delegates was "Shall or shall not the American Medical Association reaffirm its opposition to compulsory sickness insurance?" The House of Delegates replied to this question in no uncertain terms. It said:

The House of Delegates of the American Medical Association reaffirms its opposition to all forms of compulsory sickness insurance whether administered by the federal government, the governments of the individual states or any individual industry, community or similar body. It reaffirms also its encouragement to local medical organizations to establish plans for the provision of adequate medical service for all the people, adjusted to present economic conditions, by voluntary budgeting to meet the costs of illness.

The medical profession has given of its utmost to the American people, not only in this but in every previous emergency. It has never required compulsion but has always volunteered its service in anticipation of their need.

The second question propounded was based on the fact that the Committee on Economic Security, appointed by President Roosevelt, in its report to Congress on January 17 had stated tentatively eleven principles which it believes fundamental to its plan of compulsory health insurance and which apparently would form the basis of the further report on this subject to be a part of the message sent to Congress by the President on March 1.

The Committee on Economic Security, appointed by the President of the United States, presented in a preliminary report to Congress on January 17 eleven principles which that committee considered fundamental to a proposed plan of compulsory health insurance. The House of Delegates is glad to recognize that some of the fundamental considerations for an adequate, reliable and safe medical service established by the medical profession through years of experience in medical practice are found by the committee to be essential to its own plans.

However, so many inconsistencies and incompatibilities are apparent in the report of the President's Committee on Economic Security thus far presented that many more facts and details are necessary for a proper consideration.

The Wagner bill for economic security has been discussed in previous issues of THE JOURNAL. It is an act which provides for unemployment insurance and old age pensions. It also provides federal subsidies to the individual states and additional funds for maternal and child welfare, for the care of the crippled and for the United States Public Health Service. In making the bill effective, it provides for setting up a social insurance board in the Department of Labor. The House of Delegates of the American Medical Association recognized that its primary concern must be with those aspects of the measure concerned in the field of medicine and the public health. It recognized, however, that the original drafts of the Wagner bill indicated that sickness insurance also would be placed under the social service board already mentioned. Therefore the House of Delegates said:

The House of Delegates recognizes the necessity under conditions of emergency for federal aid in meeting basic needs of the indigent, it deprecates, however, any provision whereby federal subsidies for medical services are administered and controlled by a lay bureau. While the desirability of adequate

medical service for crippled children and for the preservation of child and maternal health is beyond question, the House of Delegates deplores and protests those sections of the Wagner bill which place in the Children's Bureau of the Department of Labor the responsibility for the administration of funds for these purposes.

The House of Delegates condemns as pernicious that section of the Wagner bill which creates a social insurance board without specification of the character of its personnel to administer functions essentially medical in character and demanding technical knowledge not available to those without medical training.

Recognizing the fact that the individual states are immediately concerned with the bill for sickness insurance now being proposed by the American Association for Social Security, the House of Delegates voiced its strong condemnation of this measure. In a brief statement *THE JOURNAL* called attention a few weeks ago to many of the features of this legislation which place it utterly beyond any kind of consideration from a medical point of view. The House of Delegates said:

The so-called Epstein bill, proposed by the American Association for Social Security, now being promoted with propaganda in the individual states, is a vicious, deceptive, dangerous and demoralizing measure. An analysis of this proposed law has been published by the American Medical Association. It introduces such hazardous principles as multiple taxation, inordinate costs, extravagant administration and an inevitable trend toward social and financial bankruptcy.

Throughout the country there seems to be some demand for presentation by the American Medical Association of a plan whereby county medical societies and the medical profession generally may be able to arrange with the public for a better distribution of medical service. More than ten years ago the House of Delegates recognized the desirability of such plans and authorized county medical societies, with the approval of state medical organizations, to put into effect various schemes for enabling the public, particularly in the lower income levels, to obtain adequate medical service at costs that were within their means. At the special meeting of the House of Delegates, several of these plans were brought specifically to the attention of those present. The reference committee gave careful consideration to all these plans and also to an account of some 150 plans already in operation which have been analyzed by the Bureau of Medical Economics. After this consideration, the reference committee reported:

The committee has studied this matter from a broad standpoint, considering many plans submitted by the Bureau of Medical Economics as well as those conveyed in resolutions from the floor of the House of Delegates. It reiterates the fact that there is no model plan which is a cure-all for the social ills any more than there is a panacea for the physical ills that affect mankind. There are now more than 150 plans for medical service undergoing study and trial in various communities in the United States. Your Bureau of Medical Economics has studied these plans and is now ready and willing to advise medical societies in the creation and operation of such plans. The plans developed by the Bureau of Medical Economics will serve the people of the community in the prevention of disease, the maintenance of health and with curative care in illness. They must at the same time meet apparent economic factors and protect the public welfare by safeguarding to the medical profession the functions of control of medical stand-

ards and the continued advancement of medical education requirements. They must not destroy that initiative which is vital to the highest type of medical service.

In the establishment of all such plans, county medical societies must be guided by the ten fundamental principles adopted by this House of Delegates at the annual session in June 1934. The House of Delegates would again emphasize particularly the necessity for separate provision for hospital facilities and the physician's services. Payment for medical service, whether by prepayment plans, instalment purchase or so-called voluntary hospital insurance plans, must hold, as absolutely distinct, remuneration for hospital care on the one hand and the individual, personal, scientific ministrations of the physician on the other.

Your reference committee suggests that the Board of Trustees request the Bureau of Medical Economics to study further the plans now existing and such as may develop with special reference to the way in which they meet the needs of their communities, to the costs of operation, to the quality of service rendered, the effects of such service on the medical profession, the applicability to rural, village urban and industrial population, and to develop for presentation at the meeting of the American Medical Association in June model skeleton plans adapted to the needs of populations of various types.

The importance of this special session of the House of Delegates cannot be overemphasized. It represents clearly the point of view of the medical profession as announced through its delegates elected on a truly democratic principle. Physicians who wish to preserve to the medical profession the right to say how medicine shall be practiced, their initiative in diagnosis, treatment and investigation of disease, and the intimate personal relationship that must exist between doctor and patient for the best results, will place behind these policies all the individual support they are able to muster.

THE STEROLS OF BLOOD PLASMA

Sterol, it is now generally assumed, is excreted in human feces mainly in the form of coprosterol. This is accompanied by smaller quantities of dihydrocholesterol (beta-cholestanol) and cholesterol¹. In recent years, Schönheimer and his co-workers have confirmed the early observation of Boehm that the dihydrocholesterol is excreted by the wall of the large intestine. The coprosterol of the feces is assumed to be produced by bacterial reduction of cholesterol in the intestine. Furthermore, it has been definitely established that both dihydrocholesterol and coprosterol, when administered orally, are not absorbed from the intestine. Still another sterol, allocholesterol, an isomer of cholesterol, has been considered of importance in sterol metabolism. The significance attached to this compound arises from the fact that the latter yields coprosterol when subjected to catalytic reduction *in vitro*. Furthermore, allocholesterol has been reported as the only sterol other than cholesterol that produces a significant increase in bile acid production when fed to experimental animals. However, in view of the fact that this sterol is not known to occur in nature, the evidence for its importance may merely be fortuitous.

¹ An extensive review of the physiology of the sterols is given by Bills C F. *Physiol Rev* 15 1 (Jan.) 1935.

In view of the roles that have been suggested for these various sterols in the metabolism of this class of compounds, it is surprising to find that only cholesterol has been definitely identified in body fluids. However, the similarity in properties of the substances of the sterol group makes a chemical separation and identification of other individual members a difficult problem. Schönheimer's group has evolved a method for the estimation of dihydrocholesterol in the presence of cholesterol and has applied this procedure to establish the occurrence of the former substance as a contaminant of gallstone cholesterol.

Investigators in London² have recently reported a preliminary investigation of the sterols of plasma in which an attempt was made to obtain evidence for the presence of sterols in addition to cholesterol, that appear to be of metabolic significance. With cholesterol obtained from human blood, a meticulous search was made for dihydrocholesterol and for allocholesterol. The results were negative, however the authors were led to believe that the methods employed particularly that for the identification of dihydrocholesterol are inadequate when applied to the examination of small quantities of material. It is likely that a reinvestigation of the chemical nature of the sterols of blood plasma with the employment of larger amounts of blood sterol may yield valuable information to augment the rapidly accumulating chemical and physiologic evidence of the metabolic importance of this class of lipids.

REFERRED PAIN FROM THE STOMACH

Studies of visceral and referred pain progress slowly. The factors involved are such that research demands painstaking effort and lacks the dramatic quality of some other types of medical investigation. Only occasionally do long and objective observations produce such satisfying results as those of Capps.¹ Perhaps for these reasons the study of referred pain does not occupy the important position in clinical medicine to which it is entitled.

Bolton,² whose long interest in the subject warrants special attention, has recently discussed this question in relation to the stomach. Since it has become possible to localize the majority of gastric and duodenal ulcers with the roentgen rays, he points out and to palpate them during the screen examination less has been heard of referred pain than before. The radiographer, however, employs a considerable pressure, far different from that used by the clinician when testing the abdominal wall for tenderness by lightly palpating it against the elastic resistance of the abdominal contents. The presence of painful and tender areas of the abdominal wall has been previously determined. The first and

most important objective of his investigations was to determine definitely the relation of the positions of these tender areas to the positions of the ulcers as seen by the roentgen rays. The series investigated comprised twenty-five cases of gastric ulcer, thirteen of duodenal ulcer and thirteen of painful gastric neurosis. Roentgenograms had been made of all the patients and the ulcers had been displayed on the films. All the ulcers were said to be tender to deep pressure. In the cases of neurosis the stomach was proved to be normal by roentgenograms and was free from tenderness to deep pressure.

The superficial tender areas were first determined by light palpation and marked on the surface of the skin in the upright and supine positions. In every instance these two positions were exactly the same. A glass screen made especially for this purpose was placed on the front of the body and the outline of the costal margin, the position of the umbilicus and the tender areas were marked on it with a colored pencil. Roentgenograms were then taken of the stomach in the supine and erect positions immediately after a barium meal had been given so that the stomach was full. The umbilicus was marked with a piece of metal and the ulcer which was found to be tender on screening, was shown in each position of the patient in relation to the midline and the umbilicus. The films were then placed under the glass screen so that the shadow of the umbilicus on the film and the central line of the spine corresponded with the same positions that had been marked on the glass screen and the positions in which the ulcer was seen were then marked on the glass screen. The distances of the ulcer from the midline and above or below the umbilicus in the supine and erect positions were measured in centimeters.

For the patients with gastric ulcers the tender areas as determined by light palpation, with two exceptions, were situated in the central sterno-umbilical line. In each case the area involved had a diameter of about 2.5 cm. Regardless of exact location, the points were constant in position whether the patient was erect or supine. The tenderness might be relieved or increased by contraction of the recti. In the erect position the abdomen may bulge out and increase the length of the sterno-umbilical line, but the tender point in such cases always occupied the same relative position in the line by measurement.

In eleven of the thirteen cases of duodenal ulcer the tender areas were situated in the central sterno-umbilical line. In four the tenderness was situated in the middle of this line in four in the upper part below the xiphoid process in two in the upper and middle positions and in one the whole central line was tender, the maximum point being in the upper part. The area at the ninth right costal cartilage was tender in three of the eleven and it alone was involved in two cases.

Certain types of functional disturbance of the stomach give rise to pain indistinguishable in all particular-

² Gardner, J. A. and Gainsborough, Hugh. *Biochem. J.* **28**: 1635 (No. 5) 1934.

¹ Capps, J. A. *An Experimental and Clinical Study of Pain in the Pleura, Pericardium and Peritoneum*. New York, Macmillan Company, 1933.

² Bolton, Charles. *Observations in Referred Pain*. *Brain* **57**: 211 (Oct.) 1934.

from that of an ulcer. In this group of thirteen cases the roentgenographer reported that there was no ulcer or tenderness in any part of the stomach or duodenum. All, however, showed tender areas in the anterior abdominal wall in exactly similar positions to those described in the cases of ulcer and indistinguishable from them. They are thus situated in similar well defined areas which are constant in occurrence, are fixed and immobile, and are associated with the same type of pain although the actual source of gastric irritation is different. The tender areas thus refer to the segment of the stomach irrespective of the nature of the irritant upsetting its mechanism. They are independent of any change of position of the patient and have no relation whatever to the position of the stomach. They have, therefore, the characters of referred pain and tenderness due to abnormal impulses originating in the viscus, which are conveyed to the spinal cord by its afferent sympathetic nerves, and their positions are determined by the distribution of these muscular and cutaneous nerves in the body wall, which enter the same segment of the cord as receive the afferent sympathetic fibers from the stomach.

The resulting certainty that in conditions of gastric irritation true visceral referred pain appears does not exclude, Bolton emphasizes, the probable occurrence of splanchnic pain of a different type as defined by Head, and it is certain that the tenderness obtained by the roentgenologist by heavy palpation of the ulcer also demands further investigation.

VIOSTEROL PREPARATIONS AND GALLSTONES

The widespread clinical administration of viosterol preparations has raised problems concerning several possible late effects and side actions. Among these questions is that of the formation of gallstones. Since calcium is concerned in their formation, an increase in the calcium content of the bile might predispose to gallstones. This problem is perhaps particularly acute in pregnancy, in which the incidence of gallstones is already high.

Jones and Laing¹ have recently undertaken to ascertain whether the current use of viosterol preparations might lead to an increased output of calcium in the bile in dogs. Twenty-five dogs were used in their experiments. The gallbladder was removed and the common duct or cystic duct cannulated and the flow into the cannula brought externally and collected. The dogs were kept on a standard diet with the addition of viosterol. Two concentrations were used: either the viosterol in oil, a preparation containing not less than 9,000 units (U. S. P. X. Revised, 1934) of vitamin D or a special preparation not commercially available, 100 times as potent as the former.

One hundred and ninety-three analyses of bile calcium before the administration of a viosterol preparation were made and seventy-three after the daily administration of from 5 to 10 cc of viosterol in oil, which is a dose from four to eight times larger than that ordinarily recommended as the maximum therapeutic dose for man. The data obtained were treated statistically and it was found that the mean value of normal bile calcium was 13.64 ± 0.14 mg per hundred cubic centimeters, with a standard deviation of 2.90 ± 0.10 . After the administration of viosterol the mean was 14.44 ± 0.13 , with a standard deviation of 2.57 ± 0.09 . The difference, then, calculated between the lower limit of mean after administration of the viosterol preparation and the upper limit before was only 0.53 mg per hundred cubic centimeters of bile—an essentially negligible factor. The blood calcium and bile output were not essentially modified in the experiments.

The Northwestern investigators also gave 1 cc of the special preparation before mentioned to three dogs intravenously for three or four days in succession. After this the blood calcium and bile calcium contents were increased and the output of bile was definitely decreased. It was therefore evident that doses of viosterol preparations considerably larger than would ordinarily be used in clinical practice do not raise the bile calcium concentration or modify bile output in the dog. Doses of viosterol preparations large enough to increase definitely the blood calcium level will increase the bile calcium concentration and decrease the output of bile.

Clinical confirmation of these interesting experimental conclusions is desirable. Jones and Laing hoped to obtain this confirmation on patients with chronic biliary fistulas but had not yet been able to do this. When and if confirmation is obtained, one more possible danger of viosterol administration will be eliminated.

Current Comment

THE AUTOMOBILE AND DIABETES MELLITUS

The improved high speed highways in the United States are constantly becoming more hazardous to life and limb. This is especially emphasized once a year when the total fatalities from automobile accidents are published. The shock from the ever increasing number of deaths then subsides and the slaughter of human beings goes on. Perhaps additional emphasis can be brought to bear when it is understood that the death rate from automobile accidents is now equal to that of diabetes, a disease the incidence of which has also been on the increase, even though it has been some fourteen years since Banting and his associates discovered a therapeutic preparation that would control its manifestations. The death rate in the registration area of the United States from automobile accidents in 1932 and the death rate from diabetes mellitus were the same, 21.9 per hundred thousand of population. This figure does not include deaths that followed collisions of auto-

¹ Jones, K. K. and Laing, G. H. The Effect of Viosterol on the Calcium Content of Dog's Bile. *Am. J. Physiol.* 120: 471 (Dec. 1) 1934.

mobiles with railroad trains and street cars. It is astonishing to note in the official figures of the Bureau of the Census that in 1910 the death rate from automobile accidents was only 1.8. By 1920 it had increased to 10.4, and from then each year it increased, to reach 25.2 in 1931. The excessive speed of modern cars and the fact that many persons are permitted to drive who are handicapped by temperament or character, or physical disabilities, will continue to make the total deaths a large figure. To a large extent the responsibility rests on educators, legislators and police officers.

Association News

MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 central standard time. The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

February 28	Protecting the Heart
March 7	Headache
March 14	Physical Defects

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15 central standard time. The next three broadcasts will be as follows:

February 26	Health and Education	Morris Fishbein, M.D.
March 5	Surgery in Diabetics	Leland S. McKittrick, M.D. who will speak from the National Broadcasting Company's studios in Boston by special arrangement
March 12	Food and Drug Law Revisions	Paul N. Leech, Ph.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bill Enacted—H. 30 has been enacted as chapter 49, Laws, 1935, prohibiting cities and towns of from 16 to 18 thousand population from collecting occupational taxes from physicians practicing within their jurisdictions.

Bills Introduced—H. 170 and S. 82 to amend the workmen's compensation act, propose to make the following occupational diseases compensable: (1) poisoning from lead, mercury, phosphorus, arsenic, wood alcohol, benzol, carbon bisulphide, nitrous fumes, nickel carbonyl, tetrachlormethane, radium, methyl chloride, carbon monoxide, phosphoric, sulphuric, hydrochloric or hydrofluoric acid; (2) dermatitis; (3) bursitis or synovitis; (4) compressed air illness; (5) miners' disease; (6) anthrax.

ARKANSAS

Bill Introduced—H. 281 proposes to provide a system of compensation for workmen injured by accident arising out of and in the course of their employments. An employer is to furnish an injured workman reasonable medical, surgical and hospital services and medicines not to exceed \$250 in value.

Bill Enacted—S. 126 has become a law, supplementing the medical practice act by requiring licentiates of the eclectic medical examining board to register annually with that board and to pay at that time a registration fee of \$2. Failure of an eclectic licentiate to register within the time stated will suspend automatically his right to practice, and a failure to register for three consecutive years will automatically cancel his license to practice.

A Dinner Meeting—Dr. Fergus O. Mahony, El Dorado president of the Arkansas Medical Society, was guest of honor at a dinner meeting, recently, of the Pulaski County Medical Society. Others in attendance were the following past presidents of the state society: Drs. Edward E. Barlow, Dermott, Robert Caldwell, Little Rock, Leonce J. Kosminsky, Texarkana, Herbert Moulton, Fort Smith, Frank Vinsonhaler, Little Rock, William T. Wootton, Hot Springs National Park, Darmon A. Rhinehart, and President-Elect Melvin E. McCaskill, both of Little Rock. It was said that this was to become an annual function of the Pulaski County Medical Society. Speakers were Drs. Warren H. Cole on "Causes of Failure in the Surgical Treatment of Gallbladder Disease," and Robert Elman "Reduction of Mortality in Intestinal Obstruction." Both physicians are assistant professors in surgery at Washington University School of Medicine, St. Louis.

CALIFORNIA

Personal—Dr. Albert J. Supple has been appointed health officer of South Pasadena—Oliver Peebles Jenkins, Ph.D., emeritus professor of physiology at Stanford University, died January 9, aged 84—Dr. Wilbur C. Batson, Greenville, has been appointed health officer of Plumas County, succeeding Dr. Bert J. Lasswell, Quincy.

Lectures in San Francisco—Dr. Karl Lindner, chief of the eye clinic in Vienna and successor to Prof. Ernst Fuchs, who died in 1931, will be in San Francisco, March 10, to deliver a series of five lectures and demonstrations under the auspices of Stanford University School of Medicine. Further information may be had from Dr. Hans Barkan, Stanford University Hospital, San Francisco.

Eyesight Swindlers Active Again—The California State Board of Medical Examiners reports that eyesight swindlers are active again in California. Mrs. Frances Rasmussen, San Jose, paid \$850 for a fake eye treatment with alleged radium to two men who gave the names J. O. Miles and John Doe Avery, Nov. 13, 1934. She did not report the matter to the police, however, until December 10. Two days later, December 12, a similar episode was reported to the California board from authorities in Skagit County, Wash., where the "eye specialists" fleeced an aged couple out of \$750, their life savings, by a fake cataract operation and the sale of an electric belt. A receipt for payment in full was obtained in the Rasmussen case, giving the signature "J. O. Miles, Box 417, Chicago." The names used in this case were Richard Roe alias Dr. Avery and William McBride, alias S. Clark, alias Dr. Miles, alias H. J. Pierce. These swindlers are apparently the same whose irregular activities have frequently been reported in THE JOURNAL.

Society News—A joint meeting of the Los Angeles County Medical Association and the Public Health League, January 17, was devoted to a review of the activities of the public health league; the speakers were Mr. Ben H. Read and Drs. Harry H. Wilson, Glenn E. Myers, Clarence G. Toland and John W. Crossan.—Dr. Willard J. Stone, Pasadena, among others, addressed the Clinical and Pathological Society, in Los Angeles, January 24, on "Infectious Biliary Cirrhosis with Marked Atrophy of Liver"—The Society for Neurology and Psychiatry of Los Angeles, January 16, was addressed by Drs. George H. Patterson, Los Angeles and William A. Edler, Pasadena, on "Third Ventricle Tumors" and "The Law versus Psychiatry," respectively. Otto Rank, Ph.D., Paris, France, discussed "Self-Inflicted Illness" before the society, February 15.—Dr. Arthur D. Bevan, Chicago, addressed the Los Angeles Surgical Society, February 8, on "The Present Status of the Appendicitis Problem." Dr. George W. Pierce, San Francisco, addressed the society Dec. 14, 1934, on "Reconstruction Surgery After Burns." Dr. Alfred E. Gallant was elected president at this meeting.

Bills Introduced—S. 468, to amend the medical practice act, proposes (1) to authorize courts on the application of the state board of medical examiners to enjoin the unlicensed practice of medicine and (2) to amend the title of the act so as to eliminate reference therein to osteopathy. S. 473, in effect, proposes to permit corporations and persons to qualify under the insurance laws of the state to issue medical and hospital service insurance, which "includes the contracting by way of insurance for the furnishing or procuring of hospital, medical or related professional services permitted by law and required by reason of illness, injury or disablement of the prevention thereof." S. 474 to amend the laws relating to insurance proposes that a medical and hospital service insurer, referred to in S. 473 shall not transact medical and hospital service insurance unless it has paid-in capital of at least \$25,000. In determining paid-in capital

the unexpired portion of all premiums, dues or other payments received and to be received on business then in force is to be considered as a liability. A 784 proposes to limit the retail sale or distribution of prophylactics and contraceptives to licentiates of the state board of medical examiners, of the state board of osteopathic examiners and of the state board of health. A 946, to amend the chiropractic initiative act, approved by the electors, Nov. 7, 1922, proposes, among other things, to define chiropractic as "the art and science of locating and adjusting by hand to restore to normal any abnormal anatomic relation for the purpose of removing interference with the transmission of nerve force, and also includes all natural, drugless, mechanical, hygienic, and sanitary measures incident to the care of the body when administered previous to or subsequent to an adjustment." The bill proposes also to eliminate the specific prohibition contained in the present law against the use by chiropractors of any drug or medicine now or hereafter included in materia medica. A 990 to amend the dental practice act proposes to define the following acts as unprofessional conduct in addition to the acts now specified by law: (1) advertising of a character tending to deceive or mislead the public; (2) advertising professional superiority; (3) advertising fixed prices for services; (4) advertising by means of any sign containing the representation of a tooth, bridge work or any portion of the human head; (5) employing advertising solicitors or press agents; (6) advertising free dental work or free examination; (7) advertising to guarantee any dental service; and (8) advertising to perform any dental operation painlessly. S 499, to amend the dental practice act, proposes to authorize courts on the application of the board of dental examiners to restrain the unlicensed practice of dentistry. S 512, to amend the pharmacy practice act, proposes to permit employees of a proprietor of a pharmacy, who is himself a registered pharmacist or who has a registered pharmacist regularly employed in the pharmacy to sell such drugs and medicines as general dealers in rural districts, licensed by the board of pharmacy, are permitted to sell. S 534 proposes to prohibit the admittance of any person to a private psychopathic institution, or any institution for the care or treatment of persons mentally ill or deranged without a written statement from at least two licensed physicians that they have examined the patient and that he should be admitted for care or treatment. Any person in an institution for the care or treatment of the mentally ill must be permitted to communicate at any time with whomsoever he desires. Any institution violating the provisions of this bill is to have its license revoked.

COLORADO

Bill Introduced—H 138 proposes to repeal the laws regulating the sale, distribution or possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act.

Health in Denver—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended February 9, indicate that the highest mortality rate (23.1) appears for Denver, and for the group of cities as a whole, 13.1. The mortality rate for Denver for the corresponding period last year was 12.6 and for the group of cities, 12.2. The annual rate for eighty-six cities for the six weeks of 1935 was 13.1, as compared with a rate of 12.5 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—Dr. Charles H. Boissevain, Colorado Springs, addressed the Fremont County Medical Society, Dec. 17, 1934, in Canon City, on "Public Health with Special Reference to Irrigation with Contaminated Water."—At a meeting of the San Luis Valley Medical Society in Alamosa, Dec. 15, 1934, Drs. Constantine F. Kemper and George B. Kent, Denver, discussed "Practical Endocrinology" and "Surgery of the Thyroid," respectively.—Speakers before the Medical Society of the City and County of Denver, January 15, were Drs. Hamilton I. Barnard on "Open Reduction of Fractures," Ralph H. Verploegh "Convalescent Serum in Pediatrics," Osgood S. Philpott, "Use of Serum in the Treatment of Erysipelas," and Leonard Freeman, Jr., "Drainage of the Stomach and Small Intestine."

CONNECTICUT

Dr. Mendel Awarded the Conné Medal—Lafayette B. Mendel, LL.D., Sterling professor of physiological chemistry, Yale University School of Medicine, New Haven, will be awarded the 1934 Conné Medal of the New York Chemists Club. The New York Times reported February 16 in recognition of his outstanding chemical contributions to medicine.

Dr. Mendel, who received the doctor of philosophy degree from Yale in 1893, has been associated with the institution since 1892. He has held his present position since 1921. A member of many scientific societies, Dr. Mendel is the author of "Childhood and Growth," "Nutrition—The Chemistry of Life," and "Changes in the Food Supply and Their Relation to Nutrition," and an editor of the *Journal of Biological Chemistry*. In 1927 he was awarded the gold medal of the American Institute of Chemists.

Bills Introduced—S 222 and S 458 to amend the law requiring the licensing of institutions for the treatment and care of insane persons or persons suffering from other abnormal mental or nervous conditions, propose to authorize the state department of health, rather than the governor, to license such institutions annually, to prescribe a sanitary code for the government of such institutions and to revoke licenses for stated causes. S 452 proposes to authorize the pharmacy commission to adopt rules and regulations concerning the granting to stores, not licensed pharmacies, of permits to sell proprietary and patent medicines. S 456, to supplement the pharmacy practice act, proposes that in a store not a licensed pharmacy, which has been licensed to do so by the commission of pharmacy, proprietary and patent medicines may be sold if they are in sealed containers labeled and accompanied with directions for use and with the name and address of the manufacturer or distributor. Such patent and proprietary medicines, however, must not contain alcohol in excess of the amount necessary for use as a solvent or preservative and must not contain more than 2 grains of opium, nor more than $\frac{1}{4}$ of a grain of morphine, nor more than $\frac{1}{8}$ of a grain of heroin, or 1 grain of codeine. H 845 to amend the law requiring licensed physicians, osteopaths, chiropractors, naturopaths, chiroprudists and nurses to register annually and to pay a \$2 fee, proposes to eliminate the annual fee required. H 848 proposes to prohibit the retail sale or other retail distribution of barbitol and other hypnotic or somnifacient drugs except on the prescription of a licensed physician, dentist or veterinarian. The prohibited drugs are barbitol, malonylurea, sulphonethylmethane (trional), sulphonmethane (sulphonal), diethyl-sulphone, diethyl-methane (tetralol), paraldehyde and chloral or chloral hydrate or chlorbutanol. H 852 proposes to repeal the laws regulating the sale, distribution and possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act. H 850 proposes to amend the law prohibiting the use of any drug, article or instrument for the purpose of preventing conception. The bill proposes that nothing in that law shall apply to a licensed physician nor to any patient acting under his advice when in his opinion pregnancy would be detrimental to the patient's health or to the child of such patient. H 1165, to amend the medical practice act, proposes to eliminate the requirement that an applicant for a license to practice medicine must be a citizen of the United States.

DELAWARE

Bill Passed—S 37 has passed the senate, proposing to make it the duty of physicians and midwives in attendance at childbirth (1) to use either a 1 per cent solution of silver nitrate, a 10 per cent solution of argyrol, or a 1 per cent solution of protargol, or their therapeutic equivalent, as a prophylactic against inflammation of the eyes of the new-born, (2) to make a record of the prophylactic used, and (3) to endorse the details thereof on every birth certificate.

Bills Introduced—H 95 proposes to permit licensed physicians, employees of the state board of health designated for the purpose, employees of the state board of education designated for the purpose, and any person designated by an accredited organization for the teaching of social hygiene to give lectures or instruction with respect to sex hygiene including the prevention of disease. H 94 proposes to permit licensed physicians and registered nurses to give information respecting contraception and to prescribe or supply any medicine or article adapted for the prevention of conception.

DISTRICT OF COLUMBIA

Medical Bills in Congress—S 31 and H. R. 4996 have passed the Senate and the House, providing for the issuance of a license to practice the healing art in the District of Columbia to Dr. Chester C. Groff.

IDAHO

Society News—Dr. Charles R. Scott, Twin Falls, addressed the Southwest Idaho District Medical Society at Boise, Id., Feb. 15, 1934, on economic questions and public relations. Dr. Robt. F. E. Stier, Spokane, Wash., spoke on allergic diseases. Dr. Paul H. Herron, Spokane, Wash., diseases of children.

ILLINOIS

Bill Introduced—H 236 proposes to accord to physicians dentists, drugless practitioners, nurses and hospitals treating persons injured through the negligence of others, liens on all rights of actions, claims, judgments, settlements or compromises accruing to the injured persons by reason of their injuries.

Society News—Dr Andrew C Ivy, Chicago, spoke before the Rock Island County Medical Society, February 12, on "Applied Physiology of the Biliary Tract"—At a meeting of the Will-Grundy County Medical Society, February 13, Dr Jerome R Head, Chicago, discussed "Surgical Treatment of Pulmonary Tuberculosis"—A symposium on the socialization of medicine was presented before the Eleventh Councilor District Medical Society, February 14 speakers were Drs Rollo K. Packard, Chicago, Harold M. Camp, Monmouth, and John R. Neal, Springfield.

Chicago

University News—Dr Wingate Todd Henry Willson Payne professor of anatomy Western Reserve University School of Medicine in Cleveland, addressed the Society of Sigma Xi, at the University of Chicago, February 20 on "A Study in Child Development"—Dr Gaus E. Harmon, recently appointed epidemiologist of the Chicago Board of Health has been named professorial lecturer in epidemiology and vital statistics in the department of hygiene and bacteriology, in the Division of Biological Sciences University of Chicago. He plans to give a special course in epidemiology during the spring quarter.

Society News—The Chicago Medical Society was addressed, January 30 by Dr Russell L. Haden, professor of medicine, Cleveland Clinic Cleveland on "The Recognition and Differentiation of the Anemias" and Dr Richard H. Jaffe "The Reticulo-Endothelial System"—Speakers before the Chicago Surgical Society, February 1 included Drs Alexander Brunschwig on "Large Doses of Calcium in Treatment of Metastases to Bone" Hilger Perry Jenkins "Delayed Pedicle Skin Grafts," and Harold C. Voris, "Surgery of the Frontal Lobes"—At a meeting of the Chicago Laryngological and Otolaryngological Society, February 4, Drs I. Davidsohn and John A. Cavanaugh discussed "Infectious Mononucleosis" and "Sphenoid on Parade," respectively—Dr Charles F. Geschickter, Baltimore, addressed the Chicago Orthopedic Society, February 8, on "Tumors of the Bone."

INDIANA

Personal—Dr Herman W. Smelser has been made health commissioner of Connersville and Fayette County—Dr Myron L. Habegger has been appointed health officer of Berne succeeding Dr Daniel D. Jones.

Bill Passed—H 211 has passed the house, proposing to authorize counties, cities and towns to supply insulin free of charge to citizens who are in need of insulin for treatment for diabetes and who are financially unable to purchase the drug.

Reciprocity Reestablished with Illinois—The state department of registration ratified a plan January 8, which reestablishes reciprocity licensure with Illinois. A resolution was adopted at this meeting which provides that clinical examinations will be required of licentiates from those states which require clinical examinations together with credentials. A fee of \$10 will be charged these licentiates to cover the cost of examination. The first clinical examination was given in Indiana, January 9. Three or four clinical examinations will be given annually. Reciprocity with Illinois was rescinded March 13, 1931, because Indiana applicants were required to take a clinical examination in Illinois, although licentiates from Illinois were not compelled to fill this requirement in Indiana. All members of the board were reelected at this meeting.

Bills Introduced—S 130, to supplement the pharmacy practice act, proposes to denominate stated drugs as "poisons" and to require pharmacists to keep a designated record of such drugs, showing the name of the person to whom sold, his address, and the purpose for which sold. The provisions of the bill however, are not to apply to drugs dispensed on the prescription of a licensed physician, dentist or veterinarian. S 185 proposes to prohibit any private hospital from denying any member of the immediate family of any patient access to the patient's room at any time. No person employed by a private hospital is to change or refuse to administer the treatment prescribed by the patient's physician. The board of health is to be authorized to investigate the management, facilities, accommodations and rules of any private hospital which are alleged to be discriminatory and any other practice which, in

the judgment of the board, is not conducive to the comfort, convenience or necessary privacy of patients. After a hearing, the board may make such orders as it deems necessary to correct the conditions complained of. If such a hospital shall refuse to carry out the orders of the board, the secretary of state is to revoke the authority of the hospital to transact business.

Society News—The Jay County Medical Society was addressed in Portland, January 4, by Dr Homer G. Hamer, Indianapolis, on "The Essentials of Urinary Diagnosis"—Dr Carleton B. Peirce, Ann Arbor, Mich., discussed chest diagnosis before the Muncie Academy of Medicine in Muncie, January 8—At a meeting of the Wabash County Medical Society in North Manchester, January 9, Dr Eugene B. Mumford, Indianapolis, spoke on conditions of the knee joint—Dr Eric Oldberg, Chicago, addressed the Lake County Medical Society, January 10 in Gary, on "Head Injuries"—The Tipton County Medical Society was addressed in Tipton, January 21, by Dr Edward T. Stahl, Lafayette, on fractures—At a meeting of the St. Joseph County Medical Society in South Bend, January 22, Dr Robert B. Acker, South Bend, discussed "Malignancies of the Bones"—Dr Lyman T. Rawles, Fort Wayne, spoke before the Whitley County Medical Society in Columbia City, January 15, on sickness insurance—Dr Roy D. Arn, Springfield, Ohio, discussed "Management of Fractures of the Skull and Intracranial Damage" before the Henry County Medical Society in Newcastle, January 17—The Wayne-Union Counties Medical Society was addressed January 10, by Dr George J. Garceau, Indianapolis on backache—At a meeting of the Indianapolis Medical Society, January 29, Dr Norman M. Keith, Rochester, Minn., discussed "Types of Renal Disease and Their Clinical Significance."

IOWA

Medical Referee for Emergency Relief—Dr Thomas C. Denny, Des Moines, has been appointed medical referee in handling emergency relief in Iowa. The position was created on the recommendation of Dr Knox E. Miller of the U. S. Public Health Service, following his survey of medical relief problems in Iowa. One of the first duties of Dr Denny will be to coordinate county, state and federal relief agencies through the establishment of an organization to handle medical relief. Dr Denny graduated from Jefferson Medical College in 1912. For the past several years he has served in various capacities with the Central Life Insurance Company of Iowa, holding the presidency from 1927 to 1932. He was president of the Des Moines Chamber of Commerce in 1933. Recently he was presented with the Des Moines Tribune's Community Service Award for 1934 for his services to civic and community enterprises over a period of several years.

Society News—Dr Homer W. Scott, Fort Dodge, addressed the Calhoun County Medical Society in Rockwell City, Nov. 21, 1934, on "Treatment of Acute Gonorrhea in the Male"—At a meeting of the Carroll County Medical Society in Carroll, Nov. 15, 1934, Drs Harry A. Collins and Lester D. Powell, Des Moines, discussed peptic ulcer—Dr Frank E. Burch, St. Paul, discussed conditions of the eye before the Cerro Gordo County Medical Society, Nov. 13, 1934, in Mason City—At a meeting of the Emmett and Dickinson county medical societies in Estherville, Nov. 15, 1934, Dr Herman O. McPheeters, Minneapolis, discussed "Injection Treatment of Varicose Veins"—Speakers before a joint meeting of the Pottawattamie and the Omaha-Douglas county (Nebraska) medical societies in Council Bluffs, Nov. 22, 1934, were Drs Louis D. McGaure on "Surgical Diseases of the Spleen", Frank M. Conlin, "Hereditary Factor in Disease, with Particular Reference to Diseases of Metabolism," and John A. Borghoff, "Eczema"—The Linn County Medical Society was addressed, February 14, by Drs Arthur F. Bratrud, Minneapolis, on "Ambulatory Treatment of Hernia," and Guy S. Van Alstyne, Chicago, "Diagnosis of Hypertrophic Pyloric Stenosis, with History Preoperative Preparation, the Operation, the Postoperative Management and Weight Curve." The society was addressed January 10, by Drs William H. Olmsted, St. Louis on "Vascular Diseases of the Extremities" and Louis G. Herrmann, Cincinnati, on "The Passive Vascular Exercise Method of Treating Obliterative Arterial Diseases of the Extremities."

KANSAS

Bill Introduced—S 280 proposes to repeal the present workmen's compensation act and to enact a new workmen's compensation act. An employer is to furnish to an injured workman such medical and surgical care as may be reasonably necessary to cure and relieve him from the effects of his injury.

but the cost thereof is not to exceed \$300 and the period of time during which such care must be furnished is not to exceed sixty days from the date of the accident

MAINE

Bill Introduced—H 1190 limits the retail sale or other retail distribution of sanitary or prophylactic rubber or other articles for the prevention of venereal or other diseases and infections to persons licensed by the state bureau of health

MARYLAND

Personal—Dr Arthur M Shipley has resigned from the staff of the Baltimore City Hospitals because of the increase of his duties as professor of surgery at the University of Maryland School of Medicine, Baltimore—Dr George C Halle, Easton, has been appointed health officer of Talbot County, succeeding Dr Arthur L Oilar, resigned

Tularemia—Twenty-one cases of tularemia were reported to the state department of health during the first three weeks of December as compared with seventeen during the same period of 1933 Of the twenty-one cases, twelve with three fatalities occurred in Baltimore City Since 1928 when tularemia was made a reportable disease in Maryland, 148 cases have been reported with eighteen deaths

Society News—Speakers before the Baltimore City Medical Society, February 15, were Drs Louis H Douglas 'Modern Aspects of Obstetrical Care', Samuel McLanahan 'Carcinoma of the Large Intestine, Some Conclusions from a Recent Survey,' and George McLean, 'An Unusual Case of Zinc Chloride Poisoning'—Dr Frank G Boudreau of the Health Section of the League of Nations Geneva, Switzerland gave a public lecture at the School of Hygiene and Public Health of Johns Hopkins University, January 8, on 'Medical Care Here and Abroad'

Bills Introduced—H 166 to amend the osteopathic practice act, proposes, in effect, to authorize osteopaths to make and sign death certificates H 85 proposes to authorize the issuance of a divorce if either spouse becomes incurably insane and has been committed to an institution for more than five years H 145 proposes to prohibit the retail sale and distribution of barbitol and other hypnotic and somnifacient drugs except on the prescription of a licensed physician dentist or veterinarian The drugs mentioned are to include barbituric acid, sulphonethylmethane (trisonal), sulphonmethane (sulphonol) diethyl sulphone, diethyl methane (tetralol), paraldehyde, and chloral or chloral hydrate or chlorbutanol

Another Public Health District—A new health district will be set up in the western section of Baltimore in the vicinity of the University Hospital of the University of Maryland School of Medicine by the Baltimore City Health Department it is reported This district will be similar to one established in the eastern section in 1932, comprising the sixth and seventh wards, and financed by a grant from the Rockefeller Foundation through the School of Hygiene and Public Health of Johns Hopkins University (*THE JOURNAL*, July 9, 1932, p 140) In this district the training of public health workers is carried on with a full time physician in charge as director of a branch of the city health department It was pointed out that, like the eastern health district, the new district will be organized on a basis of political divisions, including as many as are required to provide about 100,000 persons Headquarters will be established either in old hospital buildings or on adjacent hospital property It is planned to divide the entire city eventually into public health districts

MASSACHUSETTS

Institute for Tuberculosis Workers—The National Tuberculosis Association sponsored an institute for tuberculosis workers at the Hotel Statler, Boston February 4-9 Dr Frederick T Lord, Boston, president, Massachusetts Tuberculosis League, gave the opening address Other speakers included Drs Henry D Chadwick, Newton John B Hayes 2d Boston, Alton S Pope, Boston, and Nahum R Pillsbury, Braintree, and Philip P Jacobs, Ph D, New York

Radiologic Conference—The New England Roentgen Ray Society held a radiologic conference at the Hotel Statler Boston, January 25-26 Members of the staffs of Massachusetts General Boston City and Peter Bent Brigham hospitals participated in the program which covered a wide range of radiologic subjects At the dinner, Friday evening Dr Percy Brown Egypt, was toastmaster Speakers were Dr John D Camp Rochester Minn on Value of Arteriography in Periph-

eral Vascular Disease,' and Dr Merrill C Sosman Boston, 'X-Ray Conference'

Bills Introduced—H 756 proposes to amend that provision of the medical practice act which requires an applicant for a license, among other things, to have attended courses of instruction for four years of not less than thirty-two school weeks in each year in one or more legally chartered medical schools by permitting an applicant who has attended 'courses which in the opinion of the board are equivalent thereto' to be also eligible for licensure H 1629 proposes to make it a ground for divorce for either spouse to be incurably insane and to have been confined to an institution for a period of ten years or more

Society News—Dr Reginald Fitz Boston addressed the Plymouth District Medical Society January 17, on 'Present Status of Medical Economics'—The New England Ophthalmological Society was addressed in Boston, January 15 by Drs Alexander Marble Boston, on 'Studies of Blood Fat in Two Cases of Lipemia Retinalis,' and Alfred A Bielschowsky, department of research in physiologic optics Dartmouth Medical School Hanover, N H, 'Congenital and Acquired Anomalies in Fusion'—Dr Elliott P Joslin Boston, addressed the Harvard Medical Society January 8 on 'Forty Years of Diabetes'—The Springfield Academy of Medicine was addressed in Springfield February 12 by Drs Rosco G Leland director Bureau of Medical Economics, American Medical Association Chicago, on 'Current Medical Problems' and Nathan B Van Etten, New York, 'An Economic Program for 1935'

MICHIGAN

New District Health Department—The counties of Luce Schoolcraft and Mackinac were organized into a new district health department, January 1 Grants from the U S Public Health Service and the Children's Fund of Michigan made the establishment of the new district possible This brings the total to thirty-five counties having either full time county or district health department service in the state

Society News—Dr Edgar A Kahn Ann Arbor, addressed the St Clair County Medical Society in Port Huron, Dec 4, 1934, on 'Injuries and Tumors of the Brain and Cord'—Dr Arthur W McGarrah Detroit, addressed the Tuscola County Medical Society at Cass City, Dec 13 1934, on 'Conization of the Cervix'—Dr Frederic Schreiber discussed intracranial injuries before the East Side Physicians Association January 10, in Detroit

Lectures for the Public—Dr Thurman B Rice professor of bacteriology and public health Indiana University School of Medicine, Indianapolis gave a public lecture at the Book-Cadillac Hotel Detroit, January 11 on 'Common Sense in the Health Program' This was the first lecture in a series of three arranged by the public relations committee of the women's auxiliary to the Wayne County Medical Society Dr Frank L Rector, Evanston, Ill, field director of the American Society for the Control of Cancer, presented the second lecture, February 8, on 'The Nature, Curability and Prevention of Cancer'

Personal—Dr Carl F Moll, Flint, has been named physician to the Michigan School for the Deaf to succeed Dr James K Sutherland, it is reported—Dr Ferris Smith, Grand Rapids, was to address the annual session of the Royal College of Medicine, London February 1 on 'Management of Sinus Diseases'—Dr James L McCartney formerly psychiatrist and director of the classification clinic, New York State Department of Corrections at Elmira Reformatory and recently director of the Northwest Retreat Portland, Ore a guest home for convalescent or psychoneurotic persons, has been appointed on the neuropsychiatric staff of the Battle Creek Sanitarium

MINNESOTA

Bill Introduced—H 574 to repeal the laws regulating the sale distribution or possession of narcotic drugs proposes to enact what apparently is the uniform narcotic drug act

MISSOURI

Bill Passed—H 148 passed the house proposing to prohibit the sale or other distribution of marijuana

Dinner to Dr Morfit—The St. Louis Medical Society gave a dinner in honor of Dr John C Morfit, January 24 at the Missouri Athletic Association and presented him with a testimonial of esteem signed by members of the society, and a silver service Dr Morfit recently finished a term as president of the society This was the second time he had held the office, the first having been in 1907 Dr Morfit's reelection

tion was the first time in forty-eight years that a physician had been recalled to the presidency of the society. Records of the society show, however, that five other ex-presidents had been elected two or more times (*THE JOURNAL*, Jan 13, 1934, p 140).

Bills Introduced—H 327, to amend the chiropody practice act, proposes to define chiropody as "the local, medical or surgical treatments [sic] of the ailments of the human foot, except amputation of the foot or toes, or the use of anesthetics other than local, or the use of the drugs or medicines other than local antiseptics." H 388 proposes to require "all persons practicing medicine or surgery in any of its departments, professing to cure or attempting to treat the sick and others afflicted with bodily or mental infirmities, or engaging in the practice of midwifery or chiropody," to register annually with the state board of health on or before January 31 and to pay at that time a fee of \$2. If any practitioner fails to register by May 1, the board is authorized to revoke his license to practice.

Society News—The St. Louis Medical Society and the Missouri Social Hygiene Association held a joint meeting February 19, the speaker was Dr. Paul A. O'Leary, Rochester, Minn., on "The Types of Neurosyphilis in Which Malaria Therapy is Indicated." Dr. Rosco G. Leland, Chicago, addressed a special meeting of the St. Louis Medical Society February 18 on "Present Status of Social Security in Relation to Medical Economics and Health Insurance." The Jackson County Medical Society was addressed, January 22 in Kansas City, by Dr. Richard L. Sutton Jr., on "Pathological and Clinical Aspects of Early Skin Cancer." "The Immunology of Osteomyelitis" was discussed by Drs. Paul F. Stookey, James B. Weaver and Louis A. Scarpellino—Dr. Edward H. Skinner, Kansas City, discussed "Prevention and Cure of Cancer" before the Nodaway County Medical Society February 6 and Dr. Harold P. Kuhn, Kansas City, "Management of the Complications of Gallbladder Surgery." At a meeting of the Caldwell-Livingston County Medical Society in Chillicothe January 29, Drs. Louis A. Scarpellino and Ernest Kip Robinson, Kansas City, discussed the diagnosis and treatment of diphtheria and cancer of the cervix respectively.

MONTANA

Bill Introduced—H 190, to amend the workmen's compensation act, proposes to make the following occupational diseases compensable: anthrax, silicosis and poisoning from lead, mercury, zinc, arsenic, phosphorus, radium, roentgen rays and carbon monoxide.

Bills Passed—S 53 has passed the senate proposing to amend the law prohibiting the production, distribution or possession of marijuana by making a violation of the act a felony punishable by imprisonment in the penitentiary for from one to five years and/or fine of from \$500 to \$1,000. H 86 has passed the house, proposing to amend the chiropractic practice act so as (1) to define chiropractic as "the science that teaches that disease results from anatomic disrelation and teaches the art of restoring anatomic relation by adjustment by hand and the use of such other physical, thermo, and electrical methods and modalities as are necessary to the restoration of proper anatomic relation," and (2) to require a chiropractic licensee to show as a condition precedent to his right to annual reregistration that during the past year he had attended a postgraduate course in a recognized chiropractic college or has attended at least one of the "educational" programs as conducted by the Montana Chiropractic Association.

NEBRASKA

Bills Introduced—S 100, to amend the dental practice act, proposes that the following acts, in addition to the acts now stated in the law, shall constitute "unprofessional conduct" for which a licensee's license may be revoked: (1) advertising in a manner tending to deceive or mislead the public, (2) advertising professional superiority, (3) advertising prices for professional service, (4) advertising by means of large displays, glaring light signs, (5) advertising free dental work or free examinations, (6) advertising to guarantee any dental work and (7) advertising to perform any dental operation painlessly. H 219, to supplement the law authorizing the sterilization of certain socially inadequate inmates of state institutions, proposes to authorize the sexual sterilization of feeble-minded persons who are not inmates of state institutions. H 406 proposes to require a physician examining any plaintiff who has pending a court action for damages for personal injuries to file with the clerk of the court, at least thirty days prior to the trial of the case, a written report of his findings. Any

physician failing to make such a report is to be prohibited from testifying in the case and is not to be entitled to a physician's lien on any judgment rendered in the case. H 477, to amend the chiropractic practice act, proposes (1) to define chiropractic as "the science of locating and correcting interference with nerve transmission and expression between brain cells and tissue cells," (2) to permit persons who have practiced chiropractic for at least seven years and who have participated in at least twenty-five deliveries, after examination by the chiropractic board, to practice obstetrics and (3) to permit chiropractors to practice physiotherapy. H 587 proposes to prohibit the retail distribution or sale of barbitol or other hypnotic or somnifacient drugs, except on the prescription of a licensed physician, dentist or veterinarian. The term "barbitol" as used in the bill is to include the salts of barbituric acid. The term "other hypnotic or somnifacient drug" is to include sulphon-ethyl-methane (trional), sulphonmethane (sulphonal), diethylsulphon diethylmethane (tetronal), carbromal, paraldehyde and chloral or chloral hydrate or chlorbutanol. H 433 and S 218 to amend the workmen's compensation act, propose to make occupational diseases compensable. H 441 proposes to require the state to reimburse hospitals treating indigent persons injured in motor vehicle accidents. H 472, to amend the law relating to divorce, proposes to authorize a divorce if either spouse is incurably insane and has been confined in a hospital or asylum for at least ten years.

NEW YORK

Bill Introduced—A 1009 proposes to accord to charitable hospitals and to governmental hospitals, treating persons injured through the negligence of others, liens on all rights of action, claims, judgments, compromises or settlements accruing to the injured persons by reason of their injuries.

New Superintendent at Willard Hospital—Dr. Harry J. Worthing, Ogdensburg, has been appointed superintendent of the Willard State Hospital for mental patients, Willard, to succeed Dr. Robert M. Elliott, who retired Dec. 31, 1934. Dr. Elliott had been head of the institution for thirty years and in the state service for forty-five years. Dr. Worthing was formerly head of the St. Lawrence State Hospital at Ogdensburg.

Thirty-Four Deaths from Poison Alcohol—Thirty-four persons are reported to have died from alcohol poisoning in Utica and Gloversville recently. According to newspaper accounts the victims were seized with cramps, became blind, had convulsions and died in intense pain. The *Chicago Tribune* reported, January 7, that three men had been arrested and charged with first degree murder. Police said that the men who were found in Brooklyn were peddlers who had gone into the bootlegging business in Utica with a fruit store as a blind.

Society News—Dr. George E. Slotkin, Buffalo, addressed the Ontario County Medical Society at its quarterly meeting in Canandaigua, January 8, on "Nephropotosis—A Resurrected Disease." Dr. Robert H. Halsey, New York, addressed the Medical Society of the County of Nassau, January 29, on "Diagnosis and Treatment of Coronary Thrombosis." Dr. Ralph Traver, Albany, discussed "Mammoth Ovarian Cyst" at a meeting of the Medical Society of the County of Albany, January 23 and Dr. Harold A. Peck, Albany, the Friedman "rabbit" test.

Campaign Against Chiropractic Schools—The state department of education is conducting a campaign against chiropractic schools on the charge of having issued degrees without authority from the legislature or the regents, in violation of the education law. One case against the Eastern Chiropractic Institute, was disposed of Dec. 28, 1934, in the court of special sessions of New York County, when three defendants received sentences of thirty days' execution of the sentences being suspended. Similar actions are in progress against the New York School of Chiropractic and the American School of Naturopathy. Supplementing these prosecutions, an active campaign is also under way against individual chiropractors. Chiropractors are not licensed in New York and the court of appeals has held that the practice of chiropractic is the practice of medicine and that those who engage in it do so illegally.

New York City

University News—Dr. Walter Reginald Bett, London, has been appointed librarian of the College of Physicians and Surgeons of Columbia University. He is a former medical superintendent of the Princess Elizabeth of York Children's Hospital according to the *New York Times*.

Cancer Facilities—A sixteen months survey of cancer facilities in Brooklyn, recently made public by the Welfare Council, disclosed that thirty-nine borough hospitals with 8,744

beds had only twenty free beds available for cancer patients and these are all at the Brooklyn Cancer Institute. Of twenty-nine outpatient departments, only the clinic of the cancer institute made special provision for cancer patients, it was said.

Research in Child Neurology—A division of child neurology endowed by the Friedman Foundation has recently been organized at the Neurological Institute of Columbia-Presbyterian Medical Center, it was announced January 22. Dr. Bernard Sachs is director, Drs. Frederick Tilney and Louis Casamajor are associate directors. The new division will be devoted to the promotion of research on the nervous and mental disorders of childhood. The Friedman Foundation was instituted by the late Col. Michael Friedman, president of B. Altman and Company.

Society News—Dr. William Houston Toulson, Baltimore, addressed the Brooklyn Urological Society, Dec. 11, 1934, on "Resection of the Hypogastric Plexus for Urinary Bladder Disorders."—A symposium on "The Facts About X-Ray and Radium Therapy" was presented at the stated meeting of the New York Academy of Medicine, February 7, by Drs. George T. Pack, Howard C. Taylor, Jr., Anthony C. Cipollaro and Cornelius G. Dyke. Dr. Lucy D. Porter Sutton delivered the twelfth Friday afternoon lecture, February 1, on "Carditis in Children." Dr. Harold M. Marvin, New Haven, Conn., the thirteenth, February 8, on "Recent Advances in Cardiology," and Dr. Arthur M. Wright gave the fourteenth, February 15, on "Tumors of the Breast."

NORTH DAKOTA

Bill Passed—H. 8, to amend the chiropractic practice act, has passed the house. The bill proposes to define a chiropractor as one who examines, diagnoses and treats abnormal nail conditions, excrescences occurring on the feet including corns, warts, callosities, bunions and arch disorders, or one who treats medically, mechanically or by physiotherapy in a chiropractic manner the human foot.

Bills Introduced—S. 111 proposes to repeal the laws regulating the sale, distribution or possession of narcotic drugs and to enact what appears to be the uniform narcotic drug act. S. 142 proposes to permit any person to practice naturopathy who files with the recorder of deeds in the county in which he proposes to practice a diploma issued by any legally chartered school or college of naturopathy. The bill defines naturopathy "to mean the practice of the healing art as follows: The adjustment of the articulation of the human skeleton by hands or by any movements and mechanical appliances and the use of any physical forces such as air, light, water, pressure, vibration, heat, electricity, hydrotherapy, including the use of mineral salt baths and any other means or systems of therapeutics and dietetics correlated with the above therapeutic measures including nontoxic herbs and their essential oils, gums and resins applied, administered and prescribed, but shall not include the administration of drugs, the application of radium or surgery." H. 150 proposes to require all hospitals exempted from taxation to receive for treatment "any patient who desires to be treated by any system of known and generally recognized healing art to be employed at the request of the patient."

OKLAHOMA

Bill Passed—H. 46 has been passed by the house, proposing to require every hospital or physician treating a patient suffering from an injury caused by the discharge of a gun to report the facts to the proper police authorities.

OREGON

State Board Election—Dr. Robert L. Benson, Portland, was elected president of the state board of health at the annual meeting in January, succeeding Dr. Albert Mount. Oregon City, Drs. Joseph P. Brennan, Pendleton, and Frederick D. Stricker, Portland, were reelected vice president and executive secretary, respectively.

Bill Enacted—H. 112 has become a law. The bill amends the medical practice act so as (1) to permit the medical examining board to hold meetings for examinations whenever it deems it advisable, provided such meetings are held at least twice a year, the present law requiring that meetings for examination be held on the first Tuesdays of January and July; (2) to permit the board to suspend licenses as well as to refuse to issue or to revoke them for the causes now stated in the law, and (3) to add to the conduct which shall be deemed to be "unprofessional and dishonorable conduct" the obtaining of any fee through fraud or misrepresentation.

Bills Introduced—H. 241, to amend the chiropractic practice act, proposes to make a chiropractor's right to annual reregistration depend on his having attended in the preceding year at least one of the "educational" programs as conducted by the Oregon Association of Chiropractic Physicians, Inc., or on his having attended a postgraduate course in a recognized chiropractic college. H. 348 proposes to limit the sale and other distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of conception and/or venereal diseases, to licensed physicians and to licentiates of the state board of pharmacy. H. 244, to amend the naturopathic practice act, proposes (1) that the naturopathic board of examiners be appointed by the governor from lists of naturopathic physicians submitted by the Oregon Naturopathic Association; (2) to require applicants for licenses to be graduates of a school or college of naturopathic therapeutics, which teaches a resident course of not less than three years of ten months each of not less than 4,000 hours and which teaches in addition to the subjects now enumerated in the act the subjects noted below and for the minimum number of hours noted: bacteriology, 100 hours; embryology, 100 hours; jurisprudence, 35 hours; laboratory, technique of diagnosis, 75 hours; herbology, 100 hours; biochemistry, 100 hours; (3) to deny annual reregistration to licentiates who in the preceding year have not attended one or more postgraduate courses held under the direction of the Oregon naturopathic association or have not attended courses in a recognized school or college of naturopathy, and (4) to authorize naturopaths "to sign any and/or all certificates requiring the signature of a physician."

PENNSYLVANIA

Bill Introduced—H. 494 proposes to regulate the practice of chiropractic and to create a chiropractic board of examination and licensure in the department of public instruction. Chiropractic is defined as "the examination of the human spine by observation, palpation or x-ray and the adjustment of any or all misalignments of vertebrae or adjacent bones or tissues through the use of the hands."

Social Welfare Conference—At the annual Pennsylvania Conference on Social Welfare in Pittsburgh, February 19-23, physicians who participated in the program were Drs. Alexander H. Colwell, Pittsburgh, president-elect of the Medical Society of the State of Pennsylvania, who took part in a discussion of socialized medicine; Moses Behrend, Philadelphia, president of the state society, and Harold A. Miller, Pittsburgh, state director of emergency medical relief, in a discussion of one year's operation of the relief plan, and Charles H. Frazier, Philadelphia, president of the Public Charities Association of Pennsylvania, administration of public welfare services.

Society News—Drs. Holbert J. Nixon and Herbert Lund, Uniontown, addressed the Fayette County Medical Society, Uniontown, February 7, on "Hyperchromic and Hypochromic Anemias of Pregnancy" and "Physiology of Blood Clotting," respectively. Dr. Edward I. Steinberg, Erie, addressed the Crawford County Medical Society, Titusville, Dec. 5, 1934, on diseases of the skin. Dr. Ashley W. Oughterson, New Haven, Conn., addressed the Lackawanna County Medical Society, Dec. 4, 1934, on surgical treatment of pulmonary tuberculosis. The Lawrence County Medical Society at a meeting in New Castle, Dec. 6, 1934, adopted resolutions stating its disapproval of all forms of compulsory health insurance and protesting against encroachments by the state on the practice of medicine, among other matters. Speakers before the Montgomery County Medical Society, Abington, February 6, in a joint meeting with the staff of the Abington Memorial Hospital, were Drs. Roland D. Porter, Abington, George Morris Piersol, Philadelphia, and William D. Stroud, Philadelphia, in a symposium on high blood pressure.

Philadelphia

Personal—Dr. Louis D. Englerth has been appointed visiting surgeon to the Philadelphia General Hospital, succeeding the late Dr. Harvey M. Righter. Dr. Elwood R. Kirby has been appointed by the mayor a member of the Board of Health of Philadelphia to fill the vacancy caused by the recent resignation of Dr. Alexander C. Abbott after thirty-one years' service.

Thomas Oration in Urology—The Philadelphia Urological Society of the American Urological Association presented the B. A. Thomas Annual Oration, January 28, given by Dr. William E. Lower, Cleveland, on "The Control of Benign Prostatic Hypertrophy: An Experimental Review and a Clinical Prediction." Drs. Maurice D. Friedman and Alexander Randall discussed the paper.

Hatfield Lectures—Dr William H Park, Herman M Biggs professor of preventive medicine, University and Bellevue Hospital Medical College, New York, and Michael Heidelberger, Ph D, associate professor of biologic chemistry, Columbia University, delivered the Nathan Lewis Hatfield Lectures of the College of Physicians of Philadelphia, February 6. Dr Parks' subject was "Certain Clinical Aspects of Immunology" and Dr Heidelberger's, "Chemical Aspects of Antigens, Antibodies and Their Interaction."

Pittsburgh

Society News—Dr William C Bryant presented a paper on cystitis before the Pittsburgh Urological Association, February 11.—Speakers at a meeting of the Pittsburgh Academy of Medicine, February 12, were Drs Joseph S Baird on "Preventive Aspects of Some of the Acute Infectious Diseases," Paul R Sieber, "Treatment of Fracture of the Os Calcis," and Andrew B Fuller, "Basis of Symptoms in Arteriolar Disease."—Speakers who addressed the Allegheny County Medical Society, Pittsburgh, January 15, were Drs Robert C Hibbs on "Gonorrheal Arthritis," Paul Titus "Treatment of Sterility," and Rosario Charles Nucci "Carcinoma of the Cervix."

TEXAS

Bills Introduced—S 220 proposes to make it the duty of every physician or midwife, required by law to register births, to affix to the registration blanks required by law the fingerprint and the footprint of an infant which he or she delivered. H 448 proposes to render inadmissible in evidence in any civil suit any testimony concerning an autopsy unless it be shown that the nearest living relative or surviving spouse of the deceased consented to its performance and that a physician of his or her own choice was present thereat.

UTAH

Bill Introduced—H 87 proposes to make it a felony for any person to sell or furnish a narcotic drug in any form to a person under 21 years of age. The provisions of the bill, however, are not to apply to the furnishing of any narcotic on the prescription of a licensed physician.

VERMONT

Bill Introduced—S 24 proposes to create a state board of naturopathic examination and registration and to regulate the practice of naturopathy, which the bill does not define.

VIRGINIA

Personal—Dr Letcher E Trent, psychiatrist on the staff of the Veterans' Administration, has been appointed chief medical officer of the new Veterans' Facility at Roanoke. He is now director of the facility at Perry Point, Md.—Dr Charles Howe Eller, health officer of Bernalillo County, N M, with headquarters in Albuquerque, has been appointed health officer of Charlottesville and Albemarle County to succeed Dr Edwin L McQuade. Dr McQuade resigned last September to become director of rural health in the state health department.—Alfred Chanutin, Ph D, professor of biochemistry, University of Virginia Department of Medicine, Charlottesville, recently was awarded the Gibbs Prize of the New York Academy of Medicine for research on disease of the kidneys. The prize has a value of \$750 and is limited to research in that field.—Dr William A Brumfield, Farmville, has been made director of a new health district including the counties of Rockingham, Shenandoah, Page, Rappahannock, Madison and Greene, with headquarters at Harrisonburg.

WASHINGTON

Personal—Dr Arthur C Crookall, Seattle, has resigned as executive chairman of the Public Health League of Washington after many years' service. Dr Frank J Clancy, Seattle, is his successor.

Bill Passed—H Joint Memorial No 19 has passed the house, memorializing President Roosevelt and Congress to amend the Harrison Narcotic Act so as to permit narcotic addicts to be cared for through a clinic system under the direction of the United States Public Health Service acting in cooperation with city, county and state health boards.

Society News—Drs George H Anderson and Edwin J Barnett, Spokane, addressed the meeting of the Chelan County Medical Society with the Central Washington Dental Society, Dec 12 1934 at Wenatchee, on "Relation of Dental Infections to Systemic Disease" and "Dental Caries in Children," respectively.

—Dr Donald V Trueblood, Seattle, addressed the Clallam County Medical Society, Dec 12, 1934, at Port Angeles on lesions of the skin.—At a meeting of the Pierce County Medical Society, Tacoma, Dec 11, 1934, Dr Edgar F Dodds reviewed modern methods of resuscitation.—Drs Clarence L Lyon and Alphonso N Codd, Spokane, addressed the Yakima County Medical Society, Yakima, Dec. 10, 1934, on "Present Status of Thymic Hypertrophies" and "Bronchoscopy and Esophagoscopy," respectively.—Drs Torleif Torland and Irvin A Weichbrodt addressed the King County Medical Society, Seattle January 21, on "Vaginal Hysterectomy by the Clamp Method" and "Malpractice," respectively. Dr Paul J Hanzlik, San Francisco, addressed a special meeting of the society Dec. 28, 1934, on intravenous medication.—The annual meeting of the Tacoma Surgical Club, March 30, will be devoted to discussion of obstetric and gynecologic pathology, with Dr Otto H Schwarz, professor of obstetrics and gynecology, at Washington University School of Medicine, St Louis, as guest speaker.

Bills Introduced—S 148 proposes to repeal the laws regulating the sale, distribution or possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act. H 278 proposes to make it unlawful for any tax and charitable supported and tax-exempt hospital to deny any "physician, surgeon, doctor or practitioner of Allopathy, Homeopathy, Sanpractic, Osteopathy, Chiropractic, Food Science, Psychotherapy or Mediano-Therapy" the right to practice within the confines of such hospital. H 216 proposes to authorize the director of licenses to appoint an examining committee for applicants for licenses to practice naturopathy and to regulate the practice of naturopathy. Apparently applicants for such a license would be subject to the existing basic science act. The bill gives no indication of the scope of a license to practice naturopathy and apparently grants to licentiates the right to report and certify to births and deaths and all other matters pertaining to public health and requires that all such reports and certificates must be accepted as legal. S 129 proposes to regulate the practice of sanpractic. Applicants for a license to practice sanpractic need not pass the basic science examination and are examined only by an independent board of sanpractic examiners, to be appointed by the governor. Licentiates are to have the right to report births and deaths and all matters pertaining to public health and such reports must be accepted as legal. The bill defines sanpractic as "the science and art of applied prophylactic and therapeutic sanitation, which enable the physician to direct, advise, prescribe or apply food, water, roots, herbs, light, heat, exercises, active and passive manipulation, adjusting tissue, vital organs, and anatomical structure by manual, mechanical or electrical instruments or appliances or other natural agency, to assist nature restore a psychological and physiological interfunction for the purpose of maintaining a normal state of health in mind and body." Apparently licentiates are to have the right to practice obstetrics. S 137 proposes to authorize two or more adjacent counties to establish a sanatorium for the care and treatment of persons suffering from tuberculosis.

WISCONSIN

Bill Introduced—A 195 proposes to repeal the law requiring applicants for marriage licenses to present certificates from licensed physicians that they are free from venereal and contagious diseases.

Society News—The Central Wisconsin Society of Ophthalmology and Otolaryngology held a meeting in Marshfield recently, at which guest speakers were Drs Cecil S O'Brien and Dean M Lierle, Iowa City, on "Choice of Operation in Cataract Surgery" and "Nasal Allergy," respectively.—Drs Jolin Edwin Habbe and Norbert Enzer addressed the Milwaukee Roentgen Ray Society Nov 16, 1934 on "Present Trends in Cardiac Roentgenology" and "Pathogenesis in Human Silicosis," respectively.

ALASKA

Inspection of Health of Indians—Dr Vance B Murray, medical director, Alaskan Medical Service under the office of Indian Affairs, department of the interior, plans three aerial trips this year to investigate the health of Indians in every isolated spot, according to the Chicago Tribune. Nearly 30,000 natives in small and isolated settlements will be visited. Dr Murray is said to be sponsoring a program for inducing resident physicians to accept appointments as bureau deputies for part time employment by the government in treating natives in their districts. A plan whereby hospitals will accept a specified number of native patients each year at government expense is also under consideration.

GENERAL

Medical Library Meeting—The Medical Library Association will hold its annual session in Rochester, N. Y., June 17-19, with headquarters at the Sagamore Hotel. Sessions will be held at the Rochester Academy of Medicine and the University of Rochester School of Medicine.

The Birth Control Bill—The judiciary committee of the House of Representatives has tabled the bill introduced by Representative Pierce of Oregon, H. R. 2000, to relax the restrictions of the criminal code relative to the distribution of information concerning contraception and of means for accomplishing that end. The National Committee on Federal Legislation for Birth Control, of which Mrs. Margaret Sanger is chairman, has sent out an appeal asking that endorsers of its efforts send protests against this action to the chairman of the judiciary committee, Hon. Hutton W. Summers, House of Representatives, Washington, D. C. It is also asked that letters be written to the Senate judiciary committee, before which a similar bill, S. 600, is pending, urging favorable action.

Medical Fellowship at Geneva—The Institute of International Education announces that a fellowship for graduate study in the medical faculty of the University of Geneva, Switzerland is available with a stipend of 3000 Swiss francs. The stipend does not cover steamship passage and incidental expenses, matriculation and semester fees (amounting to 60 francs) or laboratory fees. A candidate must be an American citizen, a graduate of an approved medical school or the holder of a masters or doctors degree in a science related to the medical field and must have a thorough command of the French language, both written and spoken. Nominations will be welcomed. Applications must be filed before March 15 with the Secretary, Student Bureau Institute of International Education, 2 West Forty-Fifth Street, New York.

Society News—Dr. William Warner Watkins Phoenix, Ariz., has resigned as editor of *Southwestern Medicine* after twelve years' service and has been succeeded by Dr. Orville Harry Brown, Phoenix. At the annual meeting of the American Association of Oral and Plastic Surgeons in Ann Arbor, Mich. January 18-19, officers were elected as follows: Drs. Joseph Eastman Sheehan New York, president; Gordon B. New, Rochester, Minn., vice president; and Ernest Fulton Risdon, Toronto, Ont., secretary. The program consisted of clinics, demonstrations and papers. Following a dinner at the Michigan Union Drs. Frederick A. Collier and Albert C. Furstenberg, Ann Arbor made addresses on "Anatomic Aspects of Infections of the Face" and "Acute Infections of the Neck" respectively. The second day's meeting was held in Detroit, with clinics at Harper Hospital.

Reduction in Death Rates in Diphtheria, 1920-1933—The U. S. Bureau of the Census has made public a summary of the deaths and death rates from diphtheria in the registration area of continental United States for the years 1920 to 1933. In 1920 there were 13,395 deaths from diphtheria and the next year the number rose to 15,683. Thereafter it steadily declined except for a slight rise in 1927, until in 1933 there were 4,937 deaths. The rates per hundred thousand of estimated population follow the same general trend. In 1920 the rate was 15.3 and rose in 1921 to 17.6 falling thereafter except for 1927, to 3.9 in 1933. In 1920 states with the highest rates were Michigan with 23.8, Rhode Island, 21.2, and Pennsylvania, 19.8. By 1933 these had been reduced to 2.3, 1.3 and 2.4, respectively. In 1933 Kentucky had the highest death rate, 16 per hundred thousand, the next highest being West Virginia, with 10.9, Texas, 10.8, and Oklahoma, 10.6. New Hampshire had the lowest rate in 1933, with 0.4. The following states also had rates less than 1: Oregon, Utah, Vermont, Wisconsin and Wyoming.

Medical Bills in Congress—S. 1834, introduced by Senator Walsh, Massachusetts, and H. R. 4990 introduced by Representative Guyer, Kansas, propose to authorize the Reconstruction Finance Corporation to make loans to publicly and privately controlled colleges, universities and other institutions of higher learning. S. 1841, introduced by Senator Tydings, Maryland, proposes to provide medical services after retirement on annuity to former employees of the United States disabled by injuries sustained in the performance of their duties. S. 1850, introduced by Senator Sheppard, Texas, and H. R. 5179, introduced by Representative Buchanan, Texas, propose to amend an act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever by including Roger P. Ames among those honored by the act." H. R. 5278 introduced by Representative Underwood, Ohio, proposes to establish a Bureau of Veterans' Affairs in the Department of the Treasury, to repeal all exist-

ing laws relating to veterans, with the exception of those relating to insurance, and to enact an entirely new veterans' act. H. R. 5370, introduced by Representative Higgins, Massachusetts, proposes to amend existing law relating to the mailing of articles, information and devices for the prevention of conception or for producing an abortion, etc., by providing a penalty for any one who "shall knowingly cause the same to be delivered by mail according to the direction thereon, or at the place at which it is directed to be delivered by the person to whom it is addressed." H. R. 5495, introduced by Representative Collins, California, proposes to provide for entry on public lands for the purpose of establishing "health habitations." H. R. 5497, introduced by Representative Dunn, Pennsylvania, proposes to provide for the establishment of unemployment, old age and social insurance. The bill would direct the Secretary of Labor to provide for the immediate establishment of social insurance to provide compensation for all workers and farmers who are unable to work because of sickness, old age, maternity, industrial injury, or any other disability. H. R. 5600 introduced by Representative Pierce, Oregon, proposes to authorize the dissemination of information relating to the prevention of conception and articles, instruments, substances, drugs and medicines designed, adapted or intended for the prevention of conception (1) for use by any physician legally licensed to practice medicine in any state, territory or the District of Columbia, or by his direction or prescription (2) for use by any druggist in filling any prescription of a licensed physician (3) for use by any medical college legally chartered under the laws of any state, territory or the District of Columbia or (4) for use by any hospital or clinic or governmental agency chartered under the laws of the United States or licensed under the laws of any state, territory or the District of Columbia. H. R. 5693, introduced by Representative Arnold, Illinois, proposes to erect a veterans' hospital in Illinois.

Government Services

U. S. Public Health Service

Passed Asst. Surg. Walter L. Barnes relieved at Hongkong, China, and assigned at Cebu, P. I.
Passed Asst. Surg. Eddie M. Gordon Jr. relieved at Manila, P. I., and assigned at Hongkong, China.
Passed Asst. Surg. Alfred B. Geyer, relieved at San Francisco and assigned at Manila, P. I.

Positions Open for Pharmacologists

The United States Civil Service Commission announces open competitive examinations for five pharmacologists for various grades of service with the Food and Drug Administration. Entrance salaries range from \$2,600 a year for the assistant grade to \$5,600 a year for the principal grade, subject to deduction not to exceed 5 per cent during the present fiscal year, as a measure of economy, and also to a deduction of 35 per cent toward a retirement annuity. Applications must be on file not later than March 11. Full information may be obtained from the civil service board at the postoffice or customhouse in any city that has a postoffice of the first or second class, or from the commission at Washington.

New Pharmacologist in Food and Drug Administration

Dr. Erwin E. Nelson, associate professor of pharmacology, University of Michigan Medical School, Ann Arbor, has been appointed principal pharmacologist in charge of the drug division of the Food and Drug Administration. Dr. Nelson will investigate the pharmacologic action of drug and food preparations and will furnish critical advice on policies involving the effects of drugs and foods, or their ingredients or adulterants on the health of consumers. He will also act as consulting expert on formulating policies for the enforcement of the Food and Drugs Act. Dr. Nelson received the degree of doctor of philosophy from the University of Missouri and a medical degree from the University of Michigan.

CORRECTION

Corpus Luteum Hormone—In a Query and Minor Note entitled "Multiple Miscarriages" in THE JOURNAL, January 26, page 339, the words "estrogenic substance," which are the last two words on the page should have read "the hormone of the corpus luteum (progesterin)."

The Colossal Expenditure on Social Services

An official return, recently published, giving completed figures up to the end of the financial year 1932, shows the enormous strain to which Great Britain is subjected in the effort to ameliorate the conditions of the poorer section of the population. In the year 1931-1932 the expenditure on social services amounted to \$2,450,000,000. This includes sums raised both by taxes and by rates and amounts to well over half the total raised for all purposes in the country. Expenditure on social services has been steadily and rapidly rising in recent years. Even in 1929-1930, when world depression began to make itself felt, the total was \$2,340,000,000. In 1909-1910 it was only \$315,000,000, less than one seventh of the last published figure. Figures for the years subsequent to 1931-1932 are not yet available. During these years there has been some improvement in unemployment, economy measures, necessary after the disastrous expenditure of the socialist government, have been in force, and the automatic decrease in the cost of war pensions has been in progress. But now political pressure has led to the restoring of the cuts, many social services, such as housing and school feeding, are being expanded, the system of poor relief is being revised, and automatic increases are taking place in many services, such as widows' and old age pensions. It therefore seems unlikely that the taxpayer will receive any relief from his tremendous burden. Wealthy persons are taxed to the extent of about half their incomes, and persons with moderate incomes to a less but still an oppressive degree. The defense forces have been reduced to an extent unparalleled in other countries and, in the opinion of experts to a dangerous extent. This was done as an example to other countries in pursuance of a peace and disarmament policy. But the colossal increase of the cost of the social services has supplied another cause. It has not left sufficient money for the defense services. The greater part of the enormous expenditure on the social services is spent on the wage earner. When his child is born he receives a grant, free education is provided for his children and free or cheap food, medical and unemployment benefit and old-age pensions are supplied largely at the expense of the taxpayer. Yet the socialist party continues to clamor for more expenditure and pretends that the dangerous financial crisis produced by its prodigality in 1931 was simply engineered by the capitalist classes. The trouble is that in this time of universal suffrage even the conservative party has to dance to the tune of socialism. The only difference is that it tries to avoid doing it to a dangerous extent. *The Times* points out that only a tremendous effort in 1931 averted a catastrophe from which the poor would have suffered most and that, if the socialist party should be returned to power again, a similar successful effort might not be possible. At the present moment the government is spending large sums on housing and improving the administration of the unemployment dole, which far exceeds any grant to the unemployed made in any other European country. Yet it receives from the labor party leaders nothing but a shower of detraction and abuse. The inevitable hard cases, which can occur under any system, and which every effort is made to avoid, furnish an easy basis for attack and exaggeration by persons with no regard for the dangers and waste attending the distribution of public money.

International Neurological Congress

The second International Neurological Congress will be held in London from July 29 to August 2, under the presidency of Dr. Gordon Holmes. Sir Charles Sherrington was elected

president at the program conference of delegates, held in 1933, but has been compelled to resign because of ill health. At the first morning session Prof. O. Marburg will preside over a discussion on the epilepsies, their etiology, pathology and treatment. The discussion will be continued in the afternoon under the chairmanship of Prof. O. Rossi. Other subjects are the physiology and pathology of the cerebrospinal fluid, under the chairmanship of Prof. O. Foerster, the functions of the frontal lobe, under the chairmanship of Prof. H. Claude, and the hypothalamus and the central representation of the autonomic system, under the chairmanship of Prof. H. Bronwer. The afternoons will be occupied with miscellaneous papers, which will be grouped systematically under various headings as far as practicable. The triennial Hughlings Jackson lecture will be delivered during the congress by Prof. O. Foerster. The secretary of the congress is Dr. S. A. Kinnier Wilson, 14 Harley Street, London, W. 1. All neurologists, neurosurgeons, psychiatrists and any physicians or surgeons interested in neurology may become active members on paying the fee of \$7.50. Applications should be addressed to the secretary or through one of the national committees.

Cancer Research at the London Hospital

At the court of governors of the London Hospital, a report stated that while the committee was reluctant to refer to cancer research, lest false hopes be raised, it was only fair that the governors should be aware of the work that was being carried on in the cancer research laboratories. Dr. Lumsden has been working at the hospital for four years on the lines of evolving a specific body that would damage the cancer. The difficulty has been to discover an agent that would kill the cancer cells but not injure normal cells. Dr. Lumsden has evolved a serum with these properties. It has been obtained by implanting cancerous cells into an animal of a different species and obtaining serum from the blood of that animal. A stage has been reached in which the serum kills cancer cells removed from the human body without damage to normal cells similarly treated. A step further is that it is possible to implant cancer cells from one animal in another of the same species. The serum will kill the cancer so implanted. Further, it raises the resistance of the animals treated so that, the cancer having been cured, it is impossible to infect those animals again with cancer. At present the research workers are engaged in refining the serum and extracting the nonessential elements. But they emphasize that the cancer serum is only in its experimental stage and has not reached a point at which it can be tried on human beings.

Balconies for Babies in Apartment Houses

The Royal Institute of British Architects has issued a memorandum on the importance of including at least a small private balcony in working class and middle class apartment houses, large enough to take a cot for infants up to 2 years. The memorandum was submitted to the minister of health, who suggested its publication. It points out that the baby is essentially an outdoor creature and should start outdoor life to fit it for a partially indoor life. The critical years are from birth to 2 years. Fresh air is one of the first and essential preventives against colds, bronchitis, pneumonia, tuberculosis and rickets. The prevention of rickets is rendered more difficult in apartment houses without balcony accommodations. The balcony enables the mother to be within easy reach of the child and even to see it, while the roof or ground does not fulfill this requirement and the mother is therefore worried. The south is the best aspect, but east or west or even north is nearly as good. Direct sunshine is not essential and is sometimes too strong. High solid balconies are not desirable. Open wrought-iron balconies on a small plinth are the best. Some protection from cats and inclement weather is needed.

PARIS

Jan 10, 1935

The Crisis in the Medical Profession of Paris

The city of Paris forms the most important part of the department of the Seine, which has a population of nearly four million. The interests of the medical profession are looked after by an association to which all of the 4,000 physicians belong. In an address delivered Dec 7, 1934, the president of this association stated that the medical profession of the department of the Seine was suffering in an unbelievable manner from the effects of the depression. From day to day receipts decrease while expenses increase. The private hospitals, of which there are a large number in Paris, laboratories of all kinds and physicians in private practice find that they are unable to balance their budgets. Some say that there are too many laboratories and private hospitals, dispensaries and foundations of every variety, which are exempted from taxes and which compete in an unfair manner with the practitioner. A form of medical poverty is developing as the result of too much state and private medical paternalism, which results in forcing many to abandon private practice and accept merely a living wage from the state. The property of six physicians has been sold to pay taxes, and five others, poverty stricken, committed suicide. The medical profession of the smaller cities and countryside is trying its best to encourage its colleagues in Paris to maintain their rights and to insist that state and private efforts to "starve out" the practitioner must be fought with every resource at their command.

At the same meeting at which this presidential address was delivered, Dr Senechal stated that the defective social insurance laws were ruining the moral independence of the medical profession and dragging down to a condition of servitude the physician who tries to continue to carry on private practice.

The Budget of the Public Health Department

The budget for 1935 permits the department of public health of France to spend about 70 million dollars, of which 6 million represents costs of administration. The money in the budget can be divided into four groups. The first includes expenditures above 7 million dollars, such as 20 millions for aid to the aged infirm and incurable, and 15 millions for encouragement of parents to raise large families. The former of these outlays cannot be reduced. Among the second group are included expenditures between 66 thousand dollars and 7 million dollars, which are distributed for such items as aid for orphans for mothers who nurse their offspring, for dependents of soldiers, for maternity cases, for those who cannot pay for medical treatment, for the fight against tuberculosis, for premiums for births, for aid for tuberculous patients and for combating venereal disease. The other two groups include such items as aid to mothers and young children, better housing, vacation camps, physical education, nursing schools, cancer centers and inspection schools.

This list shows how complex is the present-day organization of a department of public health in a state in which many more persons receive government aid than is at present the case in the United States.

Can Finger Prints Be Changed?

Prof L. Ribeiro, director of the bureau of identification at Rio de Janeiro, Brazil, in a paper read before the Paris Academy of Medicine, Dec 18, 1934, reported his observations of changes in finger prints of lepers and those suffering from scleroderma and radiodermatitis. From a medicolegal and police point of view the Bertillon method of identification can still be considered infallible for all individuals except those included in the foregoing group of skin diseases. Ribeiro found

that in 80 per cent of 200 cases of leprosy in both sexes there was more or less change in the papillary design. One can easily understand why this should occur in leprosy patients having involvement of the nerve trunks with ankyloses and secondary atrophies, ulcerations, scar formation or mutilating deformity of the fingers. But such alterations of print design is seen also without any apparent lesion of the hand or fingers in leprosy. Microscopic study of the skin of such patients revealed active lesions with presence of the typical bacilli of leprosy of Hansen. Examination of finger prints of lepers taken several years before at the bureau of identification of Rio de Janeiro failed to show any alteration before the individual was infected. In some cases finger prints which show the typical leprosy changes become normal again after treatment.

Another disease that causes changes in finger print designs is scleroderma. During his visit in Paris, Professor Ribeiro found similar changes in cases of dermatitis due to roentgenographic work in older radiologists. He warns that one must always be on the watch for such changes in finger prints, owing to the fact that there are more than five million lepers in the world.

Blood Groups and Their Clinical Limitation

In a recent symposium before the Society of Comparative Pathology, Kossovitch said that human serum contained antibodies, termed agglutinins with respect to antigenic substances termed agglutinogens, contained in the human red corpuscles. Rode stated that the phenomenon of iso agglutination had enabled the grouping of the blood in human beings. A study of these phenomena of agglutination (iso-agglutination in the same species and hetero agglutination between different species) in wild animals may throw light on the disputed question of species. Anthropoid apes present several blood groups related to the classic ones found in the human being. Other apes show blood groupings that are alike in the same species but are less related to those of man. Domestic mammalia with their many species, all show the phenomenon of iso-agglutination. The studies made of wild animals show that their blood is much more homogeneous than that of man or of the apes. Several species belong to the same blood group. As the result of the cross breeding and acquired variations that have given rise to domestic animals, the blood acquires properties of agglutination which were not present in their savage ancestors. Troisier enumerated the arguments, which show that the blood groupings are inflexible. There are four groups, which ought to be distinguished by letters to avoid confusion. One should speak of groups O, A, B and AB. Group O does not possess any globular agglutinin, whereas group A possesses an agglutinin A, and group B an agglutinin B. Group AB, which is rare contains both agglutinin A and B. The agglutinins (in the serum) ought to be designated by the Greek letters alpha (that of group A) and by beta, the agglutinin of group B. Both of these (alpha and beta) agglutinins are found in group O, but they are absent in group AB. Blood groups do not change as the result of physical or pharmacologic influence. Certain patients followed for years retain the same grouping. One of the best arguments in favor of the permanence of groups is that the properties A and B of the red corpuscles are predominant, being subject to the mendelian laws of heredity. There is an average permanence of groups in human beings all over the world. From thirty to a hundred days after transfusion of blood of a donor belonging to a different group into a recipient of another group, one cannot distinguish any longer the red blood corpuscles of the recipient from those of the donor.

Emile-Weil and Lamy had never observed a change from one group to another. The Beth-Vincent method is almost

universally used to determine the group, by ascertaining whether or not the red corpuscles are agglutinated on a slide by two known serums. This method is not at all infallible, because of pseudo-agglutination and the possibility of overlooking true agglutination, which is slight. Such errors occur as the result of low temperatures, the presence of micro organisms and insufficient dilution of the serum. One should use only serums that have been comparatively recently obtained and whose activity has been controlled. One should never be content to employ only two serums but should take three belonging respectively to group A (Moss group 2), group B (Moss group 3) and group O (Moss group 4). By using the serum of the last named group one can verify the activity of the other two groups and thus avoid the most common source of error.

Tzanck believed that transfusion accidents are the result of faulty technic, because the blood groups themselves never change. The slight or less frequently the more serious reactions are not explained by the use of universal donors, of anticoagulants or of various forms of apparatus. In a certain number of cases the only explanation is that of an innate or acquired hypersensitivity of the recipient. This is especially true when the blood of the same donor has been previously employed without any reaction. Such exceptions do not invalidate the law of the permanence of blood groups. The Beth-Vincent method still seems to be the best. Pseudo agglutination can be excluded by the Falgairouilles kaolin or the Lattes lecithin tests.

Pausset stated that groups are observed in domestic animals but it has thus far been possible to identify only four groups in horses. Georges Rosenthal was of the opinion that the property of agglutination which is the basis of blood grouping, can present some variations even though this may rarely occur. Vignes maintained that accidents even in the absence of blood grouping are infrequent. His observations are based on a large number of transfusions, without grouping in cases of obstetric hemorrhages and in those seen in the new-born. Servantie found that even though citrated blood had been kept in a refrigerator for eight to twelve weeks there was no change in the blood grouping.

Opening of International Chemical Building in Paris

The opening of the International Chemical Building took place Dec. 2, 1934, in the presence of some of the most distinguished chemists and representatives of the French government. At the time of the celebration of the one hundredth anniversary of the birth of the French chemist Marcelin Berthelot, Oct. 25, 1927, committees were appointed in all countries to raise funds for the construction of a building instead of a monument to commemorate the services of this benefactor of humanity. Nearly a million and a half dollars was contributed, of which nearly \$700,000 is credited to the efforts of foreign members of the profession of chemistry. Great Britain and the United States contributed the major portion of the amount raised outside of France. The object of the construction of the building is to have it serve as an international center for chemists. It does not contain any laboratories but will serve only as a meeting place. In addition to committee rooms there are rooms for conferences large enough to seat 500 persons, a banquet hall with a capacity of 450 and a large auditorium with a seating capacity of 800. The organization includes five sections: reference library, publication, scientific and technical information, economic information and a section for chemical research questions. All branches of chemistry will be represented in the organization of the work of the institution. The committee in charge of the foundation includes representatives of the Institute of France, International Chemical Society and Academy of Medicine.

Vaccination Incisions and Smallpox Immunity

In Germany, the demand that vaccination incisions be shortened and their number reduced gave rise to an order by the federal minister of the interior in April 1934 to the effect that, instead of four incisions under 1 cm in length, only two shallow incisions 3 mm long should be made. But the least annoyance to the person vaccinated is not the only consideration. It is important that the immunity of the population to smallpox be adequately preserved. There are two sets of opposed opinions. According to one opinion, the slightest vaccinal infection produces complete immunity to smallpox. The other opinion is that, within certain limits, the degree of the immunity depends directly on the intensity of the vaccinal infection. Interesting experimental data on this question are obtained if one studies revaccination in a group of people in whom the intensity of the first vaccination is known. Professor Groth, director of the Bavarian Landesimpfanstalt in Munich, and Dr. Münsterer proceeded in this manner. They chose the school children of Munich who must be vaccinated at the age of 12 years so that about ten years intervene between the first vaccination in early childhood and the revaccination at age 12. In 1932 approximately 9,300 school children were examined. In 1933 7,800. Their investigation revealed that with the increasing number of scars from the first vaccination, the reactions from the revaccination of the first vaccinal type decrease, the early reactions increase, and the revaccination index is lowered. The natural conclusion is that the vaccinal immunity—the protection against infection with variola—in the 12 year old children is less, the fewer scars from the first vaccination are present. The investigations revealed plainly how weak the protection was in children who presented only one scar. These investigations brought out also that vaccinal immunity increases with increasing length and greater surface of the scars. The immunity is especially poor in children presenting very small scars, but there are slight or no differences in the degree of immunity afforded by the middle values as to length and surface area. The degree of variolous and vaccinal immunity depends to a greater extent on the number of pustules than on the size of the pustular surface. With a given length of scar or extent of scar surface, a greater vaccinal immunity is obtained the more separate incisions and separate surfaces there are. On the other hand, no relations between distinctness of the first vaccinal scars and the degree of vaccinal immunity could be established. It appeared that shallow incisions just penetrating the surface of the skin induced the same degree of immunity as was induced by the deeper incisions, provided the necessary number of insertions and the required pustular area are preserved.

These observations reveal the incorrectness of the view that the number of the vaccinal incisions does not influence the degree of immunity and that one or two vaccinal pustules have the same immunizing effect as several pustules. The variolous and vaccinal protection is inadequate with a first vaccinal scar and a total scar surface of less than about 4 cc. on the smallpox patient and the revaccinated person. The securing of a reliable smallpox immunity demands at least three vaccinal incisions from 3 to 5 mm long for the first vaccination and from 5 to 8 mm long in revaccinated persons. According to this research, these specifications constitute the lower limit beyond which the infecting vaccinal dosage, measured by the number and length of the incisions, may not be reduced without endangering the immunity of the population against smallpox. Increasing the number of incisions to that formerly required

in Germany (four) would not, to be sure, increase the number of general vaccinal disturbances, nor would it increase the immunity of the population to smallpox. Reduction of the number of incisions to two leads to a decrease of immunity, while it does not lessen the number of untoward symptoms. Reduction of the incisions to one, the authors state, is not to be considered, in spite of the fact that the course of the vaccination would be less severe, for the reason that the immunity conferred would be entirely inadequate.

Stations for the Treatment of Hydrophobia

According to the federal bureau of health, the year 1933 showed a marked increase in the frequency of bites by hydrophobic and suspected animals. In 1933 the number of bite injuries was twice that of 1932 (132 as against 64 in 1932). There were two fatal cases, neither of the patients having received Pasteur treatment. Likewise the number of treatments at the Pasteur stations increased (153 as compared with 97 in 1932). The bite injuries for which treatment was instituted were thus distributed in part: 105 cases (69 per cent) from dogs, thirty cases (20 per cent) from cats and one case each from ruminants and miscellaneous animals. In seven cases the persons concerned were not actually bitten but had come in contact with the saliva of a person who died from hydrophobia and received protective treatment as a precaution. The incidence of bite injuries caused by cats increased by 10 per cent.

In thirty-six animals (25 per cent) the presence of hydrophobia was shown experimentally and in six animals (39 per cent) only clinically. In seventy animals (46 per cent) there was only a suspicion of hydrophobia, and in forty-one the suspicion was afterward proved to be unfounded. Hence, in only 27 per cent of the persons bitten was there any serious danger of infection. In 116 cases the bite affected merely the skin. In eighty-three persons, treatment was instituted during the first four days after the injury. As a rule, the Högyes Phillips method is employed for the protective inoculation, and in one institute the Semple method is used. None of the persons receiving specific treatment contracted hydrophobia, which shows the effectiveness of such treatment when properly applied. No evidence of paralysis or other sequels developed as a result of the inoculations, as was likewise the case in the persons treated the previous year.

Regulating the Cosmetic Industry

The Hungarian ministry of commerce has issued an order in regard to the cosmetic industry, defining the sphere of activity of the industry as the care of the beauty of the healthy skin, the glossing over of its defects and the stopping of these defects, with certain restrictions. Cosmeticians must not deal with skin manifestations that point to some disease, for instance, they must not treat rashes, pustules, swellings, herpes, facial paralysis or skin and scalp diseases. They must not perform any intervention consisting of the penetration into or passing through the skin, e. g., removal of superfluous hairs, warts, moles or freckles, they must not use x-ray apparatus, ultraviolet rays or diathermy apparatus. Cosmeticians who were licensed prior to the publication of this law may continue to use their galvanic current sets or their quartz lamps, but exclusively for the removal of superfluous hairs and warts. The enactment emphasizes that barbers and manicures may carry on activity into the sphere of the cosmetic industry only if they obtain a special license. Cosmeticians must not use the doctor's title or any designations pointing to this even if

this title is legally due them. In the offices of cosmeticians, medical consulting rooms must not be maintained.

The Public Health in Hungary

Professor Dr. Cornelius Scholtz, chief of the Hungarian public health department, read a paper at the recent meeting of the Royal Medical Society on the progress made in public health affairs in the years following the war. He said that Hungary's progress is enormous. At present 83 per cent of all childbirths take place with the assistance of well trained midwives. Fifty-four per cent of all midwives take postgraduate studies. Since the war tuberculosis dispensaries have been established even in the most remote places, their number has grown from twenty-five to seventy-three. Nine new venereal disease dispensaries have been opened. The number of hospital beds has increased to 40,000 and outpatient treatment has made considerable progress in consequence of the introduction of the sanitary nursing service. Physicians in abundance are in all parts of the country, there being a decided overproduction of physicians, the detrimental effects of which are already manifesting themselves. The mortality rate has decreased from 23.3 to 15.3 per thousand and the mortality rate of tuberculosis has fallen from 3.2 to 1.9 per thousand.

Restrictions on the Advertising of Ethical Preparations

The new medical practice act forbids advertising to the public of ethical pharmaceutical preparations. Drugs and fine chemicals listed as official drugs must not be advertised in lay journals or on posters or leaflets distributed to the public, they can be advertised only in the professional press. The publication of communications that contain the results of experimentation with a new drug or with a new therapeutic method is regarded as an offense against medical ethics, be it laudatory or critical. Interviews must not be given about the action of new drugs under experimentation for newspapers. Reports on new preparations should be made by the clinic, to wit, only once, at the time of the introduction of the preparation in question, and only in professional journals. Exception may be made in sensational discoveries, in such cases leaders of clinics, when interviewed by the lay press, may give information, but even then without mentioning any individual names.

A Play Based on the Life of Semmelweis

In Vienna, a play has been produced with the title, 'Dr Semmelweis,' from the pen of Hans Refisch. The plot was taken from the life of the immortal physician. The drama deals with his struggles and the misjudgment of him by his colleagues. This drama has been produced only in Vienna, which failed to appreciate Semmelweis, seeing in this benefactor of humanity only a charlatan and driving him away. The play as a literary work is not well done, because it consists of long dialogues and tedious scientific disputes. Nevertheless the audience liked it. The leading literary reviews of western Europe have dealt with it meritoriously.

Prof Vilmos Tauffer

Prof Vilmos (William) Tauffer, a teacher of obstetrics and gynecology at the University of Budapest died in his eighty-third year. Tauffer was the first in Hungary to perform an operation for appendicitis and the first to propagandize social ideas in connection with the problems of maternity. He was the first surgeon anywhere to sew together successfully a severed ureter. During his retirement he prepared the draft of the law on the protection of maternity. Professor Tauffer had rectal cancer. His friends recommended an operation and under persuasion from his family he seemingly consented, but, knowing that his case was hopeless, he put an end to his life with a revolver.

Regulating the Sale of Drinking Waters

The *Moniteur belge* has published the new regulations pertaining to the control of the sale of drinking waters. With a view to preventing, in the interest of public health, various deceptions and adulterations, the government authorities are empowered to control (1) the collection, the treatment, the preparation and, in general, all the operations concerned in the exploitation of mineral waters and drinking waters, (2) the manufacture of artificial drinks and artificial ice, and (3) the trade in artificial ice and natural ice.

The importation of the products mentioned may be subjected to conditions to be determined by royal decree.

Unless previous authorization of the government is secured, no one will be permitted to designate a brand of drinking water by the name of the locality whence the water originates nor may any designation formed from such name be employed.

The representatives of the government charged with the enforcement of this law and of the decrees promulgated in this connection shall have at all times, ready access to the sources of supply and to the places of manufacture and sale.

Longevity of Physicians

In *Bruxelles-médical* M. Schachter takes up the subject of the longevity of physicians. Statistics based on necrologic reports concerning eminent physicians show that they are as a class, long lived. Not long ago Maurice Genty pointed out that whereas the average age of members of the Academy of Medicine in 1852 was 58 years in our day the average has increased to 69 years, which appears to indicate that the great physicians derive a profit from their art in the form of prolonged lives.

The author has collected biographic data of 2582 physicians, all of them well known through the medical literature.

Distribution of the 2,582 Physicians According to Age Groups, and the Number and Percentage of Deaths in Age Groups

Age Groups	No. of Deaths in Group	Percentage of Deaths in Group
21-30 years	51	1.97
31-40 years	143	5.53
41-50 years	274	10.61
51-60 years	481	18.62
61-70 years	639	24.63
71-80 years	648	25.44
81-90 years	311	12.04
91 years and above	35	1.35

The table shows the distribution of the 2582 physicians according to age groups, and the number and percentage of deaths in age groups. Adding together the percentage of the age groups comprising the years 60 to 90 a total of 61.84 per cent is obtained, which demonstrates the frank longevity of physicians.

The Oldest Medical Society of Belgium

In celebrating the centenary of the Société royale de médecine of Ghent, the oldest medical society of Belgium, the physicians of Ghent pointed out the vitality of Flemish medicine during the course of the nineteenth century. In a comprehensive address, Mr. Van Cauwenbergh, president of the society, recalled the many changes brought about by science in the art of medicine during the nineteenth century. He then spoke of the modifications brought about by the times, the usages and the mechanical inventions, in the life of the physician particularly the rural physician.

THE FUTURE OF SURGERY

In his address, Professor Leriche of Strasbourg discussed the modern trends and the future of surgery. At the basis of the modern trends of surgery lies the fact that Pasteur's law

and the discipline morganienne, which governed medicine in the nineteenth century, are no longer valid in all parts of the immense domain of pathology. In many cases a disease is neither the result of a microbic invasion nor the manifestation of an anatomic lesion of an organ. It is the clinical eruption, so to speak, of an old modification (scarcely abnormal) of some mechanism of habitual regulation.

Vasomotor disorders—slight peripheral nervous lesions without apparent importance—may disturb the organs. Associated with the ligaments of the knee, for example—which appear to be only a means of holding bones in place—there is an abundance of nerve fibers. Traumatism need only bruise slightly these nerve terminals, and almost immediately there appear rigidity, local increased temperature, functional weakness, muscular atrophy, rarefaction of the bones and articular effusions, all of which have been engendered by the excitations carried to the sensory apparatus of the joints.

Physiology shows how interdependent all the phenomena of life are. In the human organism, reciprocity is the watchword. A given organ does not function properly from the motor point of view unless its humoral surroundings are to its liking, and that in turn depends on the adjacent organs. A disturbance brought about in one organ, even for an instant, may produce in another organ a profound change in the secretory rhythm.

If one will analyze carefully pathologic phenomena from a physiologic point of view one will discover that most pathologic processes are at the start, diseases of the tissues or systemic diseases and not diseases of the organ.

Gastric ulcer and vesicular lithiasis before manifesting themselves clinically have had a long mute stage. It was the disordered function that created gradually the organic disease. A suitable therapy should be able to modify this mute stage.

Surgery of the sympathetic nervous system is not a term covering the technic of a few exceptional operations, it may be applicable to all diseases in which vasomotor phenomena and the disorders of nutrition of the tissues play a predominant part. It has a magnificent future. With its aid one can at least favorably modify most types of Raynaud's disease, most sclerodermias, the hyperhidroses, all the causalgias (for which there was previously no remedy), angina, and 50 per cent of the cases of asthma. With its help the long sequels of post-traumatic disorders, without fractures, can be suppressed, certain types of arthritis can be cured, the more grave symptoms of facial paralysis can be relieved, certain spasticities can be diminished, the condition of children affected with megacolon can be transformed and the like. From the results secured thus far one may judge of the future.

Surgery of the sympathetic nervous system is destined to become endocrinonervous surgery. It will be utilized in the therapy of diseases of the tissues and of diseases of nutrition. It will open up a new branch—surgery of the connective tissue and the elastic tissue.

Eye Complications, Tryparsamide and Trypanosomiasis

Addressing the Société belge de médecine tropicale, Vandenbranden and Appelmans reported that examination of their statistics of trypanosomiasis cases treated with tryparsamide revealed that about 20 per cent present eye complications, and that these conditions are especially frequent in patients with changed cerebrospinal fluid. The discovery of eye symptoms necessitates the discontinuance of arsenical treatment, as they are due to the fixation of arsenic in a nervous system sensitized by endotoxins resulting from the destruction of trypanosomes. With atoxyl the disorders are more grave with tryparsamide the cessation of treatment checks the eye complications. The visual apparatus should therefore be closely watched during treatment.

MADRID

(From Our Regular Correspondent)

Dec 28, 1934

Second Centennial of the Academy of Medicine

The Academia Nacional de Medicina of Madrid celebrated recently its second centennial. The festivities included several meetings during the medical week and an exhibition of the books of the library, which has, among other books of great importance the *Codex scientiae medicinae* of Avicenna in five large volumes, the *Regiomonte tabule directionum*, printed in 1504, *El uso de los anteojos para todo genero de vistas*, a book written by Daza Valdes, and one by Martin Martinez, and a collection of books written by Hipolito Ruiz on American plants, which for more than three centuries were a source of information for botanists and designers from all over the world.

Dr Ara, professor of anatomy of the Faculty of Medicine of Madrid, spoke on the progress of anatomy, especially in Spain, during the sixteenth to the eighteenth century which was due to the work of Servetus and Vesalius. The eighteenth century was remarkable in its progress, thanks to the devotion of anatomists to dissection, which then was a cult of ambitious workers, who were misunderstood and persecuted by the populace. Workers who wanted to see a dissection paid for an entrance fee to the dissecting room, and the fee was higher if genital organs were to be dissected. The first illustrated anatomy published was that of Juan de Arfe de Villafane. The magnificent anatomic slides made in Spain by Crisostomo Martinez and by Antonio Palomino de Velasco are still considered a prize by the libraries that have them. Palomino used to say that the application of anatomy to painting and sculpture should be moderate, in order to retain the naturalness of the pictures produced. Piquer, Virgili, Gimbernat and Bonells y Lacaba are great figures in the progress of anatomy in Spain at the last quarter of the eighteenth century. The anatomy written by Bonells y Lacaba was published at the closing of the eighteenth century. Ramon y Cajal had a favorable opinion of this anatomy.

Dr Garcia del Real, professor and academician of the Academia Nacional de Medicina, spoke on the foundation of the Colegio de San Carlos, now the school of medicine of Madrid, which was established in the epoch of Gimbernat, a scientist whose renown was as well earned as that of Michael Servetus and Ramon y Cajal. Military surgery had been so badly neglected in Spain during the eighteenth century that foreign surgeons had to be hired during military activities. Fortunately by that time Pedro Virgili took courses in universities in other European countries, returned to Spain and established a college of surgery in Cadiz, another in Barcelona, and later a college in Madrid.

Dr Marañon academician of the Academia Nacional de Medicina and successor of Ramon y Cajal in the Academia de Ciencias delivered a lecture on the medical, political and social conditions of Spain in 1734, at the time of the foundation of the academy. The eighteenth century produced great scientists elsewhere in Europe but few in Spain. Dr Marañon deplored the fact that Spaniards do not devote themselves seriously to science, although they have the ability. He said that the cooperation of scientists rather than the isolated contributions of a few mark the progress of science. That is why scientific associations, meetings and especially reunions are of value for the unfolding of new ideas and the review of old ones. There is a stimulation to present subjects worthy of discussion at meetings, and during the discussions every member endeavors to prove views aiming toward the progress of medicine.

The closing session was presided over by Martinez de Velasco, representing the government, and attended by the ambassadors

of Argentina, Austria, Belgium, Brazil, Chile, Czechoslovakia, Denmark, England, France, Germany, Italy, Mexico, Peru, Portugal, Switzerland, the United States and Venezuela. Dr Mariscal, secretary of the academy, the official speaker, reviewed the evolution of the academy, which helps the government and the city to solve problems of hygiene, medicine, prevention and control of epidemics, expert testimony in medicolegal cases, and many others. The academy also administers donations given to it for scientific or philanthropic purposes, such as the establishment of prizes for special work, of chairs for certain subjects not supported by the income of the municipality, and of scholarships both for the study of medicine in the country and of postgraduate courses abroad, as well as for the establishment of pensions for retired physicians, for widows and for minor orphans of physicians. The speaker recalled that, during the occupation of Madrid by the army of Napoleon, the physicians of the French army requested admission into the academy. Their request was granted and Larrey, Napoleon's physician, read before the academy a paper on the origin of colic in Madrid which was shown to be caused by plumbism, as lead pipes were used to carry the water supply. Larrey's article is still in the files of the academy. When Dr Mariscal ended his speech, two academicians, the youngest among the group presented the ambassadors with the diplomas of honorary academicians conferred on the scientists of their respective countries as follows: Drs Avelino Gutierrez and Bernardo A. Houssay of Buenos Aires, Annes Dias of Rio de Janeiro, Menkeberg of Santiago, Tomas Gutierrez Perrin of Mexico, Honorio Delgado of Lima, Walter Bradford Cannon of Harvard University and Rudolph Matas of New Orleans and Rafael Gonzalez Rincon of Caracas. The ambassadors made speeches acknowledging the honor conferred on their fellow citizens.

In connection with the celebration, two events deserve special mention, the first of which was the unveiling of a memorial plate in the house in which the academy was first established, which at that time was at 19 Montero Street. The plate reads: "This is the house of Dr Jose Ortega Hernandez, where the Academia Medica Matritense was established, Sept 13, 1734. The same academy, which now has the name of Academia Nacional de Medicina in commemoration of the second anniversary of its foundation unveils this memorial plate, Sept 13, 1934." The second event was a controversy in the press between a member of a national scientific center and the members of the academy with regard to the years of existence of the academy. The Academia Nacional de Medicina was established in the eighteenth century by Philip V to obtain aid in solving problems of alimentary hygiene, in the selection of places to found settlements in foreign possessions of Spain, and to solve other problems. Dr Jose Cervi, the first president of the academy was appointed by the king. Since then the academy has had in its membership the most brilliant intellects in Spain.

Dr Florestan Aguilar

The odontologist Dr Florestan Aguilar of Madrid died recently. He was educated in the United States and on returning home to practice spent his life doing good for others. When Russian dentists were in distress after the revolution, a fund was collected in several countries, especially in the United States, by the League for the Relief of Russian dentists and their families. Dr Aguilar was appointed by the league to distribute that money and he went to Russia to fulfil his duty. He was the dentist to the royal family and was the founder of the University City of Madrid and of the Sociedad Odontologica Española and of the Escuela Nacional de Odontologia. He was an academician of the Academia Nacional de Medicina of Madrid and honorary member of societies of odontology all over the world, and the founder of several dental journals.

Marriages

JOHN STEWART HOWE, Deadwood, S. D., to Miss Myra Gerichs Hicks of Dickerson, Md., in Washington, D. C., Dec. 26, 1934

LELAND POMAINVILLE, Wisconsin Rapids, Wis., to Miss Margaret Currier of Port Edwards, at Sauk City, Nov. 24, 1934

IRWIN GRIER LINTON, Washington, D. C., to Miss Nancy McMorries Moffatt of Due West, S. C., Dec. 29, 1934

WILLIAM ALBERT PRIDEAUX JR., Claysville, Pa., to Miss Thelma Taring of Aberdeen, Md., Oct. 31, 1934

FLOYD SHOCK FRANKLIN, West Haverstraw, N. Y., to Miss Katherine Denovelles of Haverstraw, January 5

ARTHUR CLAYTON SINTON JR. to Mrs. Virginia Chesterman Wickham both of Richmond, Va., January 15

THOMAS PRESTON MCKEE, Saltville, Va., to Miss Rose Clifton of Clarksburg, W. Va., January 12

GERALD BERNARD HARRIGAN, New York, to Miss Dorothy Atkinson, in Harrison, N. Y., January 31

HENRY SHIRLEY MILLETT, Brooklyn, to Miss Annie Ostrom Alexander, of New York, February 11

RALPH M. FISHER, Weston, W. Va., to Miss Dorothy Mae Johnson of Perry, Iowa, recently

HENRY JOHN ZIMMER, Mishawaka, Ind., to Miss Ruth L. Gygis of South Bend, January 16

GLEN V. RYAN to Miss Virginia Gayle Wilson, both of Indianapolis, Sept. 23, 1934

SAM GILMORE SALANDERS to Miss Katherine Easley, both of Loudon, Tenn., January 17

EDWIN J. DE COSTA to Miss Mari Helene Bachrach, both of Chicago, January 5

JOHN E. DEES to Dr. MARTA SUSAN COONS, both of Baltimore, January 7

CHARLES E. VESTLE to Miss Alma Baskett, both of Holton, Kan., recently

Deaths

John Edwards Summers, M.D., Omaha College of Physicians and Surgeons Medical Department of Columbia College, New York, 1881, following graduation he entered the army as acting assistant surgeon and was on duty at frontier posts in Wyoming nearly two years, professor of clinical surgery, University of Nebraska College of Medicine, past president of the Nebraska State Medical Association and the Medical Society of Missouri Valley member and past president of the Western Surgical Association member and in 1916 vice president of the American Surgical Association, fellow and member of the board of governors of the American College of Surgeons, formerly surgeon in chief and senior surgeon to the Clarkson Hospital and for many years chief surgeon to the Douglas County Hospital on the staffs of the Immanuel and Wise Memorial hospitals, author of "Modern Treatment of Wounds", aged 77, died, February 7, of heart disease

Roger Herbert Dennett, M.D., New York, Harvard University Medical School Boston, 1902, professor of clinical pediatrics, New York Post-Graduate Medical School, member of the American Academy of Pediatrics, director of the pediatric service and attending pediatrician to the Post-Graduate Hospital, attending pediatrician to the Reconstruction Hospital Unit, consulting pediatrician to the Willard Parker, West Side and Broad Street hospitals, New York, the Passaic (N. J.) General Hospital and the Hackensack (N. J.) Hospital, trustee to St. Lawrence University, Canton, aged 58, died, February 3, of heart disease

Alexander Dunbar McKelvey, M.D., Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1908, member of the Massachusetts Medical Society, American Academy of Ophthalmology and Oto-Laryngology and the New England Otological and Laryngological Society, fellow of the American College of Surgeons, on the staffs of the Wellesley Hospital, St. John's Hospital for Women and Toronto East General Hospital, aged 49, died, January 6, of heart disease

Gottlob Augustus Neuffer, M.D., Abbeville, S. C., Medical College of South Carolina, Charleston, 1884 member and past president of the South Carolina Medical Association, past president of the Abbeville County Medical Society, formerly

member of the state legislature, on the staff of the Abbeville County Memorial Hospital, trustee to his alma mater, aged 73, died, January 2, of coronary thrombosis

Timothy Francis Donovan, M.D., Buffalo, Columbia University College of Physicians and Surgeons, New York, 1909, served during the World War, formerly instructor in surgery, University of Buffalo School of Medicine, at various times on the staffs of the City Hospital and the Millard Fillmore Hospital, aged 50, died, January 31, in a hospital at New York, of gastric ulcer and pneumonia

Harold Jolly Beard, M.D., Youngstown, Ohio, Kentucky School of Medicine, Louisville, 1901, past president of the Mahoning County Medical Society, member of the American Academy of Ophthalmology and Oto-Laryngology, aged 54, on the staff of the Youngstown Hospital, where he died, January 30, of dilatation of the heart and cerebral hemorrhage

Andrew Watson Goodwin, M.D., Raleigh, N. C., Bellevue Hospital Medical College, New York, 1887, formerly professor of diseases of the skin and genito-urinary system, University of North Carolina School of Medicine, demonstrator and professor of anatomy, Leonard Medical School, aged 71, died, Dec. 15, 1934, of endocarditis and influenza

Anthony J. Giordano, M.D., New York, Fordham University School of Medicine, New York, 1920 member of the American Academy of Ophthalmology and Oto-Laryngology, aged 37, on the staffs of the Sexton Hospital and Columbus Hospital Extension, New York, and St. Joseph's Hospital, Yonkers, where he died, January 23, of pneumonia

James Davidson Bozeman, M.D., Fort Worth, Texas, University of Alabama School of Medicine, 1910 member of the State Medical Association of Texas, served during the World War, vice president of the staff and resident to the Arlington Heights Sanitarium, aged 47, died in January of peritonitis as the result of a ruptured appendix

Louisa Teresa Black, M.D., Denver, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895, secretary-treasurer of the Colorado Society of Clinical Pathologists for many years, aged 68, for many years on the staff of the National Jewish Hospital, where she died, January 8, of pulmonary embolus

Charles Edwin Durant, M.D., Haverhill, Mass., Harvard University Medical School, Boston, 1885 fellow of the American College of Surgeons, formerly member of the school board for many years on the staff of the General Stephen Henry Gale Hospital, aged 72, died, January 19, of heart disease

Cornelius Thomas Devine, M.D., Redondo Beach, Calif., University of California Medical Department, San Francisco, 1907, served during the World War, at one time on the staff of the Providence Hospital and the Highland Hospital, Oakland, aged 54, died, January 21, of angina pectoris

Justin Guy Ballou, M.D., Oak Harbor, Ohio, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, past president of the Ottawa County Medical Society, mayor of Oak Harbor, served during the World War, aged 52, died, January 29, of pneumonia

Alfred Ashton Johnson, M.D., New York, University and Bellevue Hospital Medical College, New York, 1925, member of the Medical Society of the State of New York, clinical assistant and visiting surgeon to the Bellevue Hospital, aged 32, died, January 21, of heart disease

Heber Olney Tucker, M.D., Santa Barbara, Calif., Johns Hopkins University School of Medicine, Baltimore, 1929, served during the World War on the staffs of the Cottage Hospital and St. Francis Hospital, aged 38, died, Dec. 19, 1934, of bronchopneumonia

Marion O. Fulcher, M.D., Wavnesboro, Ga., University of Georgia Medical Department, Augusta, 1892, member of the Medical Association of Georgia, veteran of the Spanish-American War, aged 64, died suddenly, January 16, of carcinoma of the esophagus

George Bowman, M.D., Irwin, Pa., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901 member of the Medical Society of the State of Pennsylvania, aged 60, died, January 24, in the Mercy Hospital, Pittsburgh, of pneumonia

George Moses Davis, M.D., Manchester, N. H., Dartmouth Medical School Hanover, 1889, member of the New Hampshire Medical Society, formerly on the staff of the Sacred Heart Hospital, aged 70, died, January 14, of cerebral hemorrhage

George Benson Kelso, M.D., Bloomington, Ill., University of Michigan Homeopathic Medical School, Ann Arbor, 1886 member of the Illinois State Medical Society, aged 74, died, January 27, in St. Petersburg, Fla., of coronary thrombosis

Henry R Diessner, Waconia, Minn., Hahnemann Medical College and Hospital, Chicago, 1883, formerly member of the state legislature, aged 81, died, January 11, in St Barnabas Hospital, Minneapolis, of arteriosclerosis and heart disease

Frank Abbott Dwight, Tiler, Idaho, Jenner Medical College, Chicago, 1897, member of the Idaho State Medical Association, aged 65, died, Dec. 27, 1934, in the Twin Falls (Idaho) General Hospital, of chronic myocarditis and uremia

Truman G Burris, Conway Springs Kan Northwestern Medical College, St Joseph 1893, member of the Kansas Medical Society, aged 64, died, January 10, in a hospital at Wellington, of pulmonary and cerebral emboli

Joseph A Kowalewski, Barling, Ark Kansas City (Mo) College of Medicine and Surgery, 1923 served during the World War, aged 44, died, January 17, as the result of injuries received in an automobile accident

Stanley James Tilghman @ Easton, Md University of Maryland College of Medicine and College of Physicians and Surgeons, Baltimore, 1921, aged 36, died, January 14 as the result of an automobile accident.

Edwin Kilyan Dunkel, Jersey City N J Jefferson Medical College of Philadelphia, 1899 aged 70 died Dec 7, 1934 in the New Jersey State Hospital, Greystone Park, of cerebral arteriosclerosis and myocarditis

Frederick Byron Stellwagen, Weehawken N J Albany (N Y) Medical College 1894 aged 68 was killed January 9, in Las Vegas, Nev, when the automobile in which he was driving overturned and burned

Virgil Lynn Pascoe, Newark, Ark., Vanderbilt University School of Medicine, Nashville, Tenn, 1893, member of the Arkansas Medical Society, aged 63, died, January 28, of lobar pneumonia

Wilbur M L Beatty, Centerburg, Ohio, Starling Medical College, Columbus, 1890 aged 73, died, January 30 in the Mount Vernon (Ohio) Hospital-Sanitarium, of cardiovascular-renal disease.

Kenneth Gordon Mowat, Buffalo, University of Buffalo School of Medicine, 1924, on the staff of the Millard Fillmore Hospital, aged 49, was found dead in bed, January 13, of heart disease.

Charles Clifton Tucker @ Blackstone Va., University College of Medicine, Richmond, 1903, on the staff of the Southside Community Hospital, Farmville, aged 59, died, January 28, of arthritis

Clarence Henry Dobson @ Brookline, Mass Hahnemann Medical College and Hospital of Philadelphia, 1897, served during the World War, aged 65, died, February 1, of coronary thrombosis

John Oatley Caldwell, Sharon, Mass Middlesex College of Medicine and Surgery, Cambridge, 1921 member of the Massachusetts Medical Society, aged 49, died, January 19, of pneumonia.

Leigh Maupin, Hodgenville, Ky, Hospital College of Medicine, Louisville, 1897, member of the Kentucky State Medical Association, aged 62, died suddenly, January 12, of heart disease.

Merle K. Scott, Pittsburg, Kan, University Medical College of Kansas City, 1901, member of the Kansas Medical Society, aged 56 died, Dec 10, 1934, of carcinoma of the rectum

William Wallace Kirtz Beasley, Windsor, Ont, Canada, University of Western Ontario Medical School, London 1931, aged 30, died, January 26, as the result of a fall from a train

Clarence Delos Crutcher, Los Angeles University of Nashville (Tenn.) Medical Department, 1886 aged 74, died Dec. 12, 1934, in the Los Angeles County Hospital, of uremia

Walter Brooks Brouner, New York, College of Physicians and Surgeons, Medical Department of Columbia College New York 1891 aged 65, died, January 1, of cardiorenal disease

David Perkins Oldham, Mount Juliet, Tenn. University of Tennessee Medical Department, Nashville 1901 aged 73 died, January 22, of carcinoma of the liver and gallbladder

John Nelson Coolidge, Ottawa, Ont, Canada Harvard University Medical School Boston 1894 member of the Massachusetts Medical Society, aged 68 died, January 8

William Emmett Allen, Harrodsburg Ky Hospital College of Medicine Louisville, 1903 aged 54 died Nov 2 1934 of shock following an operation for intestinal obstruction

Franklin Leeds Leister, Rochester, Minn., American Medical College St Louis, 1897 served during the World War, aged 65, died, January 12 of carcinoma of the throat

William Jacob Baumgartner, Philadelphia, Jefferson Medical College of Philadelphia, 1893, also a pharmacist, aged 64 died Dec 9, 1934, of cerebral hemorrhage

George Henry McGuffin, Cooksville, Ont, Canada, University of Western Ontario Medical School, London 1930 aged 28 was killed Dec 24, 1934, in a train wreck.

Frederick Earl Cole, Denver, Denver and Gross College of Medicine Denver 1908 formerly on the staff of St Anthony's Hospital aged 50 died, January 7, of pneumonia

John Wilson Strother, Grayson, Ky, Miami Medical College Cincinnati 1876, bank president aged 83, died, January 8 in the Stovall Memorial Hospital, of senility

Charles Daniel Toole, Detroit University of Michigan Homeopathic Medical School Ann Arbor 1915, aged 49, died suddenly, Dec. 12, 1934, of heart disease.

Mae Crellous Price Sporman, Manatee, Fla Atlanta College of Physicians and Surgeons, 1913, aged 42 died, January 1, of a self-inflicted bullet wound

Ezekial Z Hurst, Alma, Ga, University of Georgia Medical Department, Augusta, 1917, aged 41, died, January 5, of chronic nephritis and myocarditis

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request.

RECENT ADVANCES IN ARTHRITIS

To the Editor—A woman aged 65 appears to have arthritis deformans. She is of slender build and is in good health otherwise, except for a mild mucous colitis for years. The first two joints of the index finger are now deformed and the second joints of the middle fingers have the shooting pains that are the forerunners of the deposits there. I have heard that injections of cevitamic (ascorbic) acid will cure this condition. Have you any information as to this? If so what route, frequency and dosage are recommended? What are the toxic symptoms of overdosage? I understand that Dr. Szent-Györgyi, the director of the Institute of Medical Chemistry Szeged University, Hungary has been working on this problem. What results has he obtained in arthritis deformans treated with this acid? What other treatments are well regarded or have produced cures of this disease? Would you consider thyroid extract favorably as an auxiliary measure? What about diet? (I have no reference books to speak of at hand.) Please omit name and address. M D Washington

ANSWER—Those who do not subscribe to one of the variants of the theory of infection in relation to chronic arthritis generally argue that it is the result of some metabolic derangement or defect in alimentation. The exact nature of this derangement, if such exists, has never been demonstrated. It has been suggested that arthritis is the result of a metabolic disturbance that is related chiefly to carbohydrates or proteins, sulphur or calcium, and so on. Recently (reflecting the trend of medical investigation in general) it has been suggested that a deficiency in vitamin might be the cause of, or at least prepare the soil for, chronic arthritis.

In 1921 McGarrison (Studies in Deficiency Disease) reported the production of atony of the intestine and degeneration of the intestinal mucosa in the colons of monkeys by feeding diets that were high in carbohydrates and that previously had been placed in the autoclave. Rowlands (Rheumatoid Arthritis, Is It a Deficiency Disease? *Proc Roy Soc Med, Sec. Compar Med.* 20 41 [April] 1927), noting that intestinal atony was a feature in certain cases of arthritis, propounded the question "Is rheumatoid arthritis a deficiency disease?" Fletcher of Toronto has extended this view and is inclined to believe that a lack of vitamin B may be responsible (The Nutritional Factor in Chronic Arthritis, *J Lab & Clin Med* 15 1140 [Aug] 1930).

None of these investigators, however, have conclusively produced experimental arthritis in animals by the use of a diet that was deficient in vitamins. In the absence of particular data, it has become the fashion of some to give arthritic patients diets that are rich in all vitamins, stressing chiefly vitamin B, which is given in yeast and in wheat germ. The intake of carbohydrate is reduced to enhance the utilization of vitamin B.

The chemical nature of vitamin C (cevitamic acid, introduced as ascorbic acid) apparently has been identified as a "hexuronic acid", it is available both in natural and in synthetic forms. This substance is present in the adrenal glands and in certain varieties of paprika (*Capsicum annum*). Szent-Györgyi and his colleagues have kept guinea-pigs, on experimental diets, practically free from scurvy by the administration of the juice of paprikas. They also have noted that cevitamic acid readily disappears from the adrenal glands of animals that are on a vitamin C-free diet (Svirbely, J. L., and Szent-Györgyi, Albert. The Chemical Nature of Vitamin C, *Biochem J* 27 279, 1933. Szent-Györgyi. Die medizinische Bedeutung des Vitamines C, *Deutsche med Wchnschr* 60 556 [April] 1934).

Cevitamic acid is too new to warrant many of the exaggerated therapeutic claims that have been made for it. Investigators have reported striking benefits from its use in pyorrhea (when due to vitamin C deficiency), certain types of hemophilia ("not the hereditary type"), certain forms of hemorrhagic nephritis, the disfiguring discoloration of Addison's disease, and several other diseases. These require further clinical confirmation. Arthritis is not mentioned in the preliminary press reports (*Science News Letter* Sept. 22, 1934, *Time* 24 34 [Sept. 17] 1934).

For current concepts on the diagnosis and treatment of the various types of chronic arthritis, the correspondent is referred to "A Primer on Rheumatism and Chronic Arthritis," which has been prepared by the American Committee for the Control of Rheumatism, published by the American Medical Association. This booklet can be obtained for 15 cents from the offices of the American Medical Association.

TREATMENT OF MISSED ABORTION

To the Editor—A patient aged 20 years, three months pregnant had labor pains because of severe overexertion. I was able to stop them for four or five days with morphine. Then they became severe and the water broke. After that I tried to complete the miscarriage by using quinine and small graduated doses of solution of pituitary but every thing quieted down and now for two weeks there have been no changes. In the face of the ruptured membranes what would be your plan of procedure in this case? Would there be any possibility of the membranes closing up again and holding water? What is the danger to the mother and to the fetus? Please omit name.

M D, Indiana.

ANSWER—Most likely this is a case of missed abortion, that is, the fetus is most likely dead but has not been expelled. One way to verify the death of the fetus is to perform an Aschheim-Zondek or Friedman test. If these tests are negative it is almost certain that the fetus is dead. However, if these tests are positive, it is by no means certain that the fetus is alive, because, if the chorionic villi are normal and active, these biologic tests are nearly always positive. The chorionic tissue often continues to live for a time after the fetus perishes. Of course, clinical evidence of the death of the fetus will be obtained if the uterus fails to grow larger. After death of an ovum the uterus usually diminishes in size and becomes firmer. It is possible for a fetus to continue its existence even after the membranes have ruptured. Occasionally the opening in the membranes is closed over, more liquor amni forms, and the fetus continues to grow to term. More rarely, after the liquor has drained away the fetus continues its development outside the membranes. In such cases deformities may result. In most cases of missed abortion, especially where fetal death is of only a few weeks duration, it is advisable to wait until a spontaneous abortion takes place. Generally the nausea that may have been present ceases and the breasts become smaller. Occasionally disagreeable symptoms arise after fetal death and among them are a foul vaginal discharge, malaise, loss of weight, and slight elevation of temperature. If the patient is upset mentally by the condition it may be best to empty the uterus, provided it is certain that the fetus is dead. Usually a three months pregnancy can be removed by means of a dilation and curettage. Occasionally, however, the cervix is rigid and a vaginal hysterotomy becomes necessary. Frequently bleeding is excessive after a curettage for missed abortion, because the uterine musculature does not contract properly, hence one should be prepared to pack the uterine cavity after the operation. In the present case it is safe to wait, but while waiting to see whether the uterus will continue to soften and grow or become harder and smaller, coitus should be forbidden.

INFECTIVITY OF SYPHILIS

To the Editor—What textbooks I have speak of the man but little of the woman as to the time that must elapse to the point where she will not be liable to infect any one with syphilis. I am speaking of cases that have received little or no treatment in women. Textbooks say that a man can be infected and after a period of five years even if untreated may marry and reproduce healthy children and not infect his wife that is probably will not. Textbooks state (which one can see is the truth) that a woman may be infected early in life and if untreated, the disease will lead to abortions or cause the patient to give birth to syphilitic children through her reproductive period in life. Here is the question I wish to ask your opinion on. Is there any period in the life of women who have contracted syphilis and have received no treatment (say like the male after a period of five years) in which she would not infect the male? For example A woman aged 60 was married but separated from her husband and divorced him fourteen years ago owing to his bad habits with other women. They had two children in their early married life who are living and in good health. She had no abortions. This woman came under the care of a physician recently suffering from what she thought was rheumatism in the legs. The physician suspected tabs and the report from two different laboratories indicated the blood four plus. She could give no history of any primary or secondary symptoms. She has lived a clean life which leads one to think that she has been infected from fourteen to twenty years. For example if she had married five years ago and her husband was free from syphilis, could she have infected her husband? Please omit name.

M D, Illinois

ANSWER—The question of the infectivity of syphilis in both the male and the female is still far from conclusively answered. This is especially applicable, of course, to untreated cases. The observations that have been made on the infectivity of the semen have thrown a good deal of question into the so-called five year rule. The problem is even more difficult to evaluate in women, and the question as to just when a woman ceases to be able to infect her sexual partner cannot be categorically answered at this time. None the less, a large body of clinical evidence tends to show that, even after the second year of the untreated disease, infectivity begins to decline quite rapidly and between the fifth and the tenth year syphilis is comparatively seldom transmitted in the ordinary circumstances of life.

The occurrence of fetal infection is hardly an exactly parallel case, for the risks assumed in sexual exposure, even though repeated, can hardly compare with the risk to which the fetus is subjected in its direct contact with the maternal circulation. It is certainly true that the closest students of the question hesitate to name a time at which a woman with untreated syphilis can become pregnant without a significant possibility that she will infect her child.

ALLERGIC CONJUNCTIVITIS

To the Editor—I have been perplexed in the treatment of what I believe to be a case of simple chronic conjunctivitis. The patient is a young adult whose work takes him in and out of doors. His general health is very good. He is not troubled with any intranasal or paranasal disease. He has complained of burning and grittiness of both eyes for the last three years. The condition is usually worse toward evening when there is an associated slight photophobia. There have been some periods when he has had comparative amelioration of the symptoms; this is noted more especially in the summer months. An examination of the eyes reveals some congestion of the conjunctival vessels with occasional strands of fibrin lying low in the sac. The redness is most marked in the palpebral conjunctivitis. At times there is some evidence of actual warmth in the eyelids. He has a small refractive error (slight astigmatism in one eye and slight hypermetropia in both eyes) which is corrected with glasses. The following treatment has been rigorously adhered to during the course of the disease: at first, frequent boric lotion washes later combined with small amounts of zinc sulphate instillations; sodium hydrocarbonate also used later with no better effect. Silver preparations have not been resorted to. Will you kindly suggest further lines of treatment? Please omit my name. M D, New York.

ANSWER—It is possible that the case in question is one of allergic conjunctivitis and it would be well to subject the patient to intradermal tests in the hope of finding the common substances to which he is sensitive. Subsequent withdrawal one by one of these substances, without changing the local therapy, would furnish absolute proof. If this course is not feasible, massage of the anesthetized conjunctiva with a glass rod is suggested. This should be performed from one to three times a week, followed each time by adequate flushing of the conjunctival sac with physiologic solution of sodium chloride or boric acid solution. The persistent use of silver nitrate or any of the colloidal silver salts is to be deprecated. Mild astringents, such as 0.5 per cent zinc sulphate or 2 per cent resorcinol will be found to be of greater value.

PSEUDOMUCINOUS CYSTADENOMA OF OVARY

To the Editor—A woman, aged 30, has a pelvic tumor, diagnosed after considerable study in a university hospital in 1930 as pseudomucinous cystadenoma of the ovary. Previous to this date two laparotomies were performed and tumor masses removed. During the past five years considerable high voltage roentgen therapy has been given. The general nutrition and general physical condition are as good today as in 1930. The lower part of the abdomen and pelvis contains a large tumor mass fixed to the abdominal wall and surrounding structures. What is the prognosis of the case, considering the diagnosis as correct? How much roentgen treatment can be given and at what intervals? Kindly omit name.

M D Wisconsin

ANSWER—Pseudomucinous cystadenoma of the ovary is generally regarded as a benign lesion. The two important complications of this disease are implantation metastasis and malignant degeneration. In most instances the recurrence is benign and represents a direct, local implantation rather than a true metastasis. This complication is reported to occur in from 15 to 67 per cent of cases observed by various authors in the literature. In some cases microscopic examination of recurrences has failed to reveal any epithelial cells but only gelatinous material. The more important but less frequent complication consists of malignant degeneration. Recurrences as late as twenty-one years after operation have been recorded. Hofmeier has observed that the incidence of recurrence after the removal of one ovary is 4.9 per cent, after removal of both ovaries, 1.9 per cent.

The inability to determine from clinical examination whether carcinomatous degeneration has occurred renders it important to irradiate the lesion as if it were carcinoma. It is impossible to state with any degree of accuracy the prognosis in this case. Much would depend on whether the present mass represents an unremoved portion of the original growth or an entirely new growth. In the latter instance the prognosis would be much more serious than in the former. It is also impossible to outline the course of roentgen therapy without a knowledge of the response or lack of response to previous treatment, nor is it possible to state what dosage can be given without a knowledge of all the detailed factors of the previous irradiation. In general it is advisable to administer the radiation in divided daily doses to the extent that the condition of the skin will permit.

TRAUMA SYPHILIS AND OPTIC ATROPHY

To the Editor—A Negro aged 23, was hit on the left temporal region and over the left eye and also on the occipital regions of the head with a gun during a holdup. He was unconscious, his left eye swelled up and closed completely and the left supra-orbital region was lacerated. He was removed to a hospital where he remained for ten days. Roentgen examination revealed a questionable fracture of the left parietal area. The left eye remained swollen for two or three weeks and then loss of vision set in. The ophthalmologist said that there was an injury to the optic nerve. For several months, previous to the trauma the patient was receiving arsphenamine therapy for syphilis. His Wassermann reaction was 4+. His vision before the accident was good because he had passed his vision test for a chauffeur's license. Is the loss of vision a result of the trauma per se? Is it the result of the syphilitic condition per se? Could the trauma have activated a latent or dormant syphilis of the optic nerve? Would the patient have lost his vision on account of the syphilis had not the trauma supervened at this time? In toto did the trauma or the preexisting disease namely syphilis cause the loss of vision? Please mention references. Kindly omit name.

M D New York

ANSWER—This case is not described fully enough to permit of an absolute answer. Knowledge of the condition of the optic nerves and the visual fields is essential. Judging from the description, it is most probable that the skull fracture involved either the orbit or the margins of the optic foramen and that as a result of that fracture there was a hemorrhage into the orbit, probably within the sheaths of the optic nerve, with resultant pressure and atrophy of the nerve. It is unlikely that a primary optic atrophy, due to syphilis, could be initiated by the trauma although interstitial keratitis of syphilitic origin may be instituted by trauma. Much can be found on this subject in "Injuries of the Eye," second edition, by Würdemann, and the Kurzes Handbuch der Ophthalmologie, volume 4, by Cramer.

EPHEDRINE IN DYSPNEA

To the Editor—I am interested in the employment of ephedrine intramuscularly in the treatment of allergic paroxysmal dyspnea. Suppose that a physician wished to use one-fourth grain (0.016 Gm.) of ephedrine hydrochloride. I wish to know: 1. What is the effective dose? 2. Can it be used safely after epinephrine? 3. Suppose that the patient is a child aged 4 years with a severe asthmatic attack and one to which one is planning to give epinephrine chloride from 4 to 6 minutes: what amount of the ephedrine given intramuscularly would be an equivalent therapeutically? I am aware that the hyporemic dose is stated to be one-sixth grain (0.01 Gm.) in Guiman. R F CRITTENDEN, M D, Los Angeles.

ANSWER—1. The effective dose depends on the age of the patient and the severity of the paroxysm just as the dose of epinephrine must vary. An average dose of ephedrine hydrochloride intramuscularly will range from 0.01 to 0.03 Gm. (one-sixth to one-half grain). Dosage and repetition of dosage will depend on the effect on the asthmatic attack and on the occurrence of any of the usual, well known untoward reactions on the part of the patient.

2. It may be used after epinephrine but it is not advisable because the bad effects will be prolonged. Furthermore, there would be no necessity for administering ephedrine when the favorable effect of epinephrine has been secured.

3. There is no ephedrine equivalent to epinephrine in time of response. The dose of ephedrine comparable with the dose of epinephrine stated would be about 0.016 Gm. (one-fourth grain) therapeutically and about 0.02 Gm. (one-third grain) physiologically.

It must be remembered that from 25 to 30 per cent of individuals are unable to tolerate ephedrine. If treatment with ephedrine is desired, it is best to mix epinephrine solution 1:1000 and ephedrine 3 per cent solution in the proportion of 1:2 and give this mixture in the usual epinephrine dosage. There is a decided disadvantage in giving ephedrine when epinephrine is subsequently found necessary because the synergistic effect that may occur even several hours later may cause severe headaches and other disagreeable reactions in a large percentage of individuals.

TACHYCARDIA—FUNCTIONAL APPRAISAL OF HEART

To the Editor—1. What is the significance of paroxysmal tachycardia occurring in a man, aged 34, without other evidence of heart disease and in general good health? 2. What is the value of Tjörstedi's cardiac efficiency factor (pulse pressure/systolic pressure)? Does a coefficient above 40 indicate a worse prognosis than one below 20? 3. For practical purposes what tests will give the most accurate information concerning the functional capacity of the heart?

C F BARBER, M D, Felicity, Ohio

ANSWER—1. Paroxysmal tachycardia in a man of 34, without other evidence of heart disease almost always is a benign although occasionally a troublesome arrhythmia. There is no known cause for it, although it is regarded as neurogenic.

The prognosis for life is excellent. When attacks occur rarely, no treatment is indicated. When the attacks are frequent, constant digitalization, or the constant administration of 0.2 Gm (3 grains) of quinidine sulphate, three times daily, may be helpful.

2 It is not established that any of these methods of calculation are of much help in prognosis.

3 There are no practical tests of the functional capacity of the heart that are as good as the ordinary appraisal obtained by an intelligent history and careful physical examination.

ALIMENTARY GLYCOSURIA OR DIABETES

To the Editor—The other evening just by chance I happened to examine my own urine. I found that the Benedict's solution turned green (test for sugar). This specimen was passed about one hour after my evening meal which consisted of two slices of pork chops two buttered potatoes one tomato (sugar on it for sweetening) three slices of rye bread two patties of butter one cup of coffee (with two teaspoonfuls of sugar) and eleven canned cherries with the syrup. Two hours after the meal I tested the urine again but there was no change in the Benedict's solution. It remained blue. Nevertheless I got rather scared at finding this sugar in the first specimen. On the following evening I cut down on the carbohydrates somewhat but there was still a faint green color with Benedict's solution. Could this be a case of alimentary glycosuria? I have noticed a moderate degree of polyuria lately likewise a polydipsia. My mother who is 68 years old has some sugar in the urine. What should I do to rule out diabetes in my own case? In what way can alimentary glycosuria be differentiated from diabetic glycosuria? Two hours after my evening meal I do not find a change in the Benedict's solution i. e. it stays blue. Physicians are advised to test urines within two hours after a hearty meal. In this case how can one differentiate an alimentary from a diabetic glycosuria? M D Pennsylvania

ANSWER—So called alimentary glycosuria cannot be distinguished from mild or early diabetes mellitus and, indeed may occur in moderate diabetes when the kidney threshold for sugar is raised. However, before deciding that this is really an 'alimentary glycosuria' one should identify the reducing substance that appears in the urine as dextrose (fermentable sugar). One should also determine the blood sugar both in the fasting state and after food, in order to rule out the possibility of a lowered kidney threshold for sugar (renal diabetes). When the renal threshold is only moderately lowered glycosuria may occur only after meals and thus simulate an alimentary glycosuria. The fact that the correspondent has recently noticed moderate degrees of polyuria and polydipsia, and the fact that the mother exhibits glycosuria, both favor the diagnosis of diabetes mellitus.

READING MATERIAL IN PSYCHONEUROSES

To the Editor—I have had occasion to treat several cases of psychoneurosis. I have often felt that recommending some reading material in certain of these cases might help considerably from the standpoint of psychotherapy—from the standpoint of helping these patients gain some insight into their mental maladjustments. In 'The Treatment of Psychoneurosis in General Practice' (THE JOURNAL Oct 13 1934) Dr Lauren H. Smith of Philadelphia speaks of the study and reading a patient does in connection with special written material on mental hygiene. Would you please send me some suitable references? M D New York.

ANSWER—What the patient reads and studies in relation to acquiring more knowledge about mental hygiene or in relation to working out personal problems is not as important as the way in which he studies and what help he has in getting some understanding about the reading. There are countless numbers of books and articles many of which are good, some of which are bad but few of which do not contain some material of value. The following books are a few that have been used with different patients. They are not all suitable for all personalities and one must be familiar with each book to know how adequate or safe it is for any one patient. They are books however which can be recommended unquestionably and which are used constantly.

Discovering Ourselves by Strecker and Appel published by the Macmillan Company

Just Nerves and Intelligent Living by Austen Fox Riggs.

Outwitting our Nerves by Dr Josephine Jackson

Other books that can be used in part or in whole, depending upon the patient, are

The Wholesome Personality by Dr William Burnham

Understanding Human Nature by Dr Felix Adler

Fear by Dr John Rathbone Oliver

What Men Live By by Dr Richard Cabot

How to Be Happy Though Human and Nervous Breakdown by Dr W. Beran Wolfe

Isolated reading without discussion with the patient as to the relation of the reading to personal problems, or without certain interpretations can confuse instead of help a patient.

ALOPECIA AREATA—DERMATITIS FROM DEODORANTS

To the Editor—I A farmer, aged 37 whose general health is excellent and whose past history is essentially negative shaves himself. One month ago he noticed a small area the size of a dime (18 mm. in diameter) located just to the left of the midline on the lower jaw that was hair free. This area has increased in size and now is the size of a quarter (24 mm in diameter). The area is smooth surrounded by normal beard growth. The change is abrupt. The bearded portion next to the bare area is perfectly normal. Apparently the roots of the beard are gone. 2 Are either Deodo or Odorono capable of producing a dermatitis? Please omit name M D, New York.

ANSWER—1 The appearance of a smooth area, devoid of inflammation, in which the hair is absent and the patch is surrounded by a normal hair growth, is the picture seen in that type of hair loss known as alopecia areata.

2 Deodo and Odorono are both capable of producing a dermatitis or folliculitis of varying degree in individuals with sensitive skins. The reaction is most probably due to the aluminum salts contained in these preparations.

SEXUAL INTERCOURSE TO FREE VESICLES OF GONOCOCCI

To the Editor—What truth is there to the following statement: In the declining stages of gonorrhea sexual intercourse (with the use of a condom to prevent transmission of the disease) is not only harmless but of some value in that it empties the seminal vesicles and prostate gland very much like a rectal massage does. Please omit name and address. M D California

ANSWER—The general consensus among urologists seems to be that gentle massage of the prostate and seminal vesicles is preferable to sexual intercourse during the declining stages of a gonorrheal urethritis. The possibility is always present that the patient may still harbor gonococci and that the condom may break with resultant infection of the partner. Therefore it is much better to massage these patients than to recommend sexual intercourse.

BASEBALL FINGER

To the Editor—A young woman has a 'baseball finger' with the usual drop or flexion of the distal portion. What can be done to remedy this some four weeks after injury? Please omit name. M D Washington

ANSWER—Four weeks is a long period. The simplest and best treatment is immobilization in the overcorrected position, that is hyperextension of the distal phalanx of the affected digit. This can be accomplished by plaster of paris, a wood splint or preferably a splint like one described by Dr Lewin in THE JOURNAL Oct 3 1925 page 1059, and June 30, 1928, page 2102. This splint is made of aluminum, is light, is easily adjusted, is permeable to x rays, can be immersed in water and is inexpensive. The pattern of the finger is made and sent to the brace maker, who molds and fits the splint.

NO FOOT AND MOUTH DISEASE IN UNITED STATES

To the Editor—In Queries and Minor Notes in THE JOURNAL, January 19 page 239 in the reply to M D Alabama concerning a boy affected with a throat and mouth trouble the statement is made that the association with cows and goats or the use of milk butter or cheese from sources where foot and mouth disease is present might aid in the diagnosis. The fault of this statement lies in the fact that foot and mouth disease does not exist in the United States and it could not exist in Alabama or elsewhere in this country without bringing great headlines in the newspapers and an army of disease fighters to the scene without an hour's delay. Foot and mouth disease is one of those sweeping animal plagues that leave no doubt of their presence. Foot and mouth disease has broken out in the United States several times during the last fifty years but each time it was promptly stamped out. The vigil against it is constant. In view of the wide foreign circulation of THE JOURNAL, this remark by one so highly rated in the medical profession does an injustice to the veterinary service of the United States and can do incalculable harm to our struggling live stock industry. It implies that this grave plague exists among the domestic animals of the United States notwithstanding official declarations to the contrary.

L A MERILLAT D V M Chicago

PTOSIS OF EYELIDS

To the Editor—In Queries and Minor Notes in THE JOURNAL Dec 22 1934 the item entitled Ptoxis of Upper Eyelids interested me as from August to December 1928 I was a victim of ptoxis of the upper right eyelid. A complete examination by several specialists proved negative. Ten days after I discontinued cigaret smoking the ptoxis cleared up and I have never had any trouble since. Needless to say I have not smoked since. Please omit name and state. M D

California July Examination at Los Angeles

Dr Charles B Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at Los Angeles, July 24-26, 1934. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Ninety-four candidates were examined, 89 of whom passed and 5 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
College of Medical Evangelists	80 1 80 3 80 4 80 9 81 2 82 6 82 8 83 8 83 3 83 3	(1934)	80

California July Examination at San Francisco

Dr Charles B Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at San Francisco, July 10-12, 1934. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and twenty-three candidates were examined, 118 of whom passed and 5 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent

West Virginia October Report

Dr Arthur E McClue state health commissioner, reports the oral, written and practical examination held in Martinsburg Oct 29-31, 1934. The examination covered 11 subjects and included 110 questions. An average of 80 per cent was required to pass. Six candidates were examined, all of whom passed. Eleven physicians were licensed by reciprocity. The following schools were represented:

Book Notices

Amebiasis and Amebic Dysentery By Charles F. Craig, M.D., M.A., F.A.C.P., Professor of Tropical Medicine and Head of the Department of Tropical Medicine, School of Medicine, Tulane University of Louisiana, New Orleans, La. Price \$5. Pp. 315 with 54 illustrations. Springfield, Ill.: C. V. Mosby Co., 1934.

This timely monograph was written to help the physician in the diagnosis, prophylaxis and treatment of amebiasis, which, although not so understood by every one, includes amebic dysentery. The first chapters deal with the historical aspects of the disease and with its geographic distribution. The disease is world wide and, in the United States, its incidence is from 5 to 10 per cent. Included is a discussion of the organism *Endamoeba histolytica*, and Craig clearly points out the importance of the typical sluglike, directional movement of fresh trophozoites. Tables of surveys are listed to demonstrate certain epidemiologic aspects of amebiasis. However, since most surveys are of the sick, or at best of institutionalized subjects, there may be a reasonable doubt as to their application to the general population. Craig believes that the chief method of transmission is by food handlers, although he recognizes other methods as having been demonstrated. The pathology is treated in two chapters, and evidence is offered that carriers always have lesions due to cytotoxicity and necrosis of superficial epithelium, which is constantly taking place. He does not accept Koford's conclusions that joints are invaded in arthritis or lymph nodes in Hodgkin's disease. Symptomatology is thoroughly covered in relation to the healthy carrier, the carrier who is considered healthy but has very mild symptoms and the patient who has recurrent attacks, and in relation also to acute and chronic amebiasis, with and without various complications and with and without sequelae. Methods of diagnosis receive adequate treatment in two chapters that deal with clinical examinations and laboratory methods, including smears, stains and cultures, and complement fixation tests, the last he recognizes as still experimental. Prognosis, prophylaxis and treatment are covered in the last chapters with the admonition that there is no single drug and no single method that can be effective in all cases. In general, he favors emetine for the acute condition, followed by chinofon and for carriers chinofon alone. The book is handsomely illustrated and the style is that of an experienced teacher, direct and forceful. Craig's position in this country in the field of amebiasis is unchallenged and this monograph is a worthy climax to his thirty years of experience in this work.

Radium and Cancer. A Monograph By H. S. Souttar, D.M., M.Ch., F.R.C.S., Surgeon, London Hospital. Cloth. Price 21/- Pp. 387 with illustrations. London: William Heinemann Ltd. 1934.

In his introduction the author points out the difficulties encountered in the radium treatment of cancer and adds that "the success obtained is due to the clinical instinct of the surgeon in each case, to his wide experience and the incommunicable way in which he applies that experience to the problem which each case presents." He could not have stated the problem more clearly and forcibly. Unfortunately, it is not yet recognized that the execution of a correct irradiation is not a simple technical procedure or a prescription to be filled by a technician under the general direction of a clinician not familiar with the principles of radiotherapy. Actually the problem is so complex that there is no field in medicine in which the clinical instinct and skill of the clinician are more important in the result than in the radiotherapy of cancer.

Recognizing the difficulties that beset the surgeon as regards the physics of radiation and the difficulties encountered by the physicist in comprehending the associated pathologic and clinical problems, the monograph is presented in an effort to unite the physical properties of radium with the clinical application of this agent to certain forms of cancer. The first nine chapters deal with the physics of radiation. These are followed by chapters on biologic effects, measurement of dose, and technique of radium application. The last eight chapters discuss the treatment of cancers of the skin, mouth, breast, esophagus, rectum, bladder, prostate and cervix. The physics of radiation is presented accurately, concisely and clearly. The selection of the material has been well made and this portion of the

monograph constitutes an excellent presentation of the subject for clinicians especially interested in the uses of radium. The chapters dealing with the construction of various types of radium applicators and radium beam therapy are of interest and practical value.

In discussing the general principles of radiotherapy the author believes that gamma rays of radium present a very definite advantage over x-rays since, owing to their shorter wavelength, they have proportionately greater penetration. It is easier to maintain a uniform field in deep seated lesions with radium than with x-rays, and although the use of greater distances with x-rays permits the delivery of a larger proportion of the energy in the depth, the use of such volumes presents important disadvantages. Thus there is general agreement that x-rays produce more constitutional disturbance than do gamma rays of equal adequacy, probably because of the more complete absorption which x-rays undergo in the tissues.

The latter part of the book, dealing concisely with the radium treatment of certain forms of cancer, contains much useful and practical clinical information. It is interesting to note that the author prefers the use of radon seeds to removable platinum needles in the treatment of carcinoma of the breast although he is impressed by the technique and results of Kevnes. It is difficult to visualize an accurate placement of 100 or 150 radon seeds throughout a breast. In this respect the author is not supported by the principles of filtration and uniformity of distribution or by the comparative results of the two methods in the hands of various workers. On account of the dangers involved and poor results obtained, the author's use of radon seeds in the treatment of carcinoma of the esophagus is generally not acceptable.

On the whole, the author is to be congratulated on his achievement of presenting in clear and concise form an interesting treatise on the physics of radium and its clinical application in the treatment of certain forms of cancer. The book can be recommended to all physicians who have a special interest in the radiotherapy and especially radium therapy of cancer.

Anaesthesia and Analgesia in Labour By Katharine G. Lloyd Williams, M.D., B.S., Honorary Anaesthetist to the Royal Free Hospital, including the Obstetrical and Gynaecological Units. With a foreword by Dame Louise McIlroy, D.B.E., D.Sc., M.D., Professor of Obstetrics and Gynaecology, London (Royal Free Hospital) School of Medicine for Women, Farnhield. Price \$2. Pp. 96 with 12 illustrations. Baltimore: William Wood & Company, 1934.

This book describes the administration of drugs and anesthetics commonly used in England not only in hospitals by trained anesthetists but also in homes by general practitioners. The author emphasizes that thus far the ideal anesthetic has not been found. Most of the information given in the book is based on the extensive experience of the author. The material is divided into chapters describing the use of anesthetics and analgesic drugs in the first stage of normal labor, the second stage of normal labor, the third stage of labor and the resuscitation of the new-born, anesthesia for abnormal deliveries, and analgesics and anesthetics in complicated labors. Contrary to most American anesthetists and obstetricians the author considers chloroform to be a comparatively safe anesthetic in the second stage of labor. She does not believe that ether is as satisfactory as chloroform or nitrous oxide and oxygen. Ethylene has not been used much in England. The author believes that spinal anesthesia is excellent for cesarean sections, but it should be emphasized that pregnant women are far more susceptible to the dangers of spinal anesthesia than are nonpregnant individuals and the death rate is much higher among the former. The author singularly points out that spinal anesthesia should be used in cardiac cases but a bad heart in a pregnant woman is a double contraindication to the use of spinal anesthesia. Likewise the author recommends the use of morphine before administering a spinal anesthetic but since this and other alkaloids are respiratory depressants, they may lead to harm when a spinal anesthetic is used. Direct infiltration anesthesia is far simpler and safer than spinal anesthesia and should be used more frequently than it is at the present time. The book does not contain anything new but it is an excellent summary of the subject of analgesia and anesthesia in labor.

Psychotherapie Ein Lehrbuch für Studierende und Ärzte Von Privatdozent Dr. Heinrich Kogerer Cloth Price 10 marks Pp 167 Vienna Wilhelm Maudrich 1934

The German language psychiatric literature seems recently to have changed. Until a few years ago German works on psychiatry were so detailed that their usefulness to the American practitioner was curtailed because of their ponderousness. Today, works such as Kogerer's impress one with their superficiality. Fully half of it treats of the symptoms of mental disorders rather than of their treatment. In this respect the book is inferior to the general run of American psychiatric textbooks intended for students. Organic psychoses for which there are now some treatments susceptible of being carried out by the general practitioner (for whom this book was intended) are hardly mentioned. The first half of the book contains a number of interesting comments, which are not particularly new but which are well expressed and might prove useful to a reader who has not gained his knowledge of psychotherapy through experience. In this part there is a chapter describing the attitude and make up of the psychotherapist which does not agree entirely with the experience of American practitioners. The chapter on psychotherapeutics in general attempts to cover the whole field in a relatively short space. No particular stress is laid on such new and useful techniques as those devised by Freud and Adler. While the use of these techniques is mentioned only casually, the author's interest in psychoanalysis is shown in a number of the case studies in which he mentions the use of analysis. These case studies are relatively short and there are about sixty-three of them. There are two pages devoted to social psychiatry at the end of the book. The knowledge to be derived from this book would seem to be useful to only those psychiatrists who are interested in keeping up with the literature on the subject. For practical purposes the information given is explained sufficiently well in American works to make the reading of this book unnecessary.

The Medicolegal Necropsy A Symposium held at the Twelfth Annual Convention of the American Society of Clinical Pathologists at Milwaukee Wisconsin June 9 1933. Edited for the Society by Thomas B. Magath. Cloth Price \$2.50 Pp 167 with 63 illustrations. Baltimore Williams & Wilkins Company 1934.

The contents of the book are introduction, by Frederic E. Sondern, the medicolegal system of the United States, Oscar T. Schultz, the medicolegal necropsy, Charles Norris, performing the medicolegal necropsy, A. V. St. George, pathological anatomy of death by drowning, Edward L. Miloslavich, toxicology in the medicolegal necropsy, Alexander O. Gettler, medical examiner's findings in deaths from shooting, stabbing, cutting, and asphyxia, Harrison S. Martland, report on necropsies by a joint committee representing the New York Academy of Medicine, the New York Pathological Society and the Metropolitan Funeral Directors' Association. These articles are reprinted from the January 1934 issue of the *American Journal of Clinical Pathology* except the article by the joint committee, which appeared in the *Archives of Pathology* 14: 701 (Nov.) 1932.

Die Irrtümer der Psychoanalyse Eine Irrlehre mit einem genialen Kern. Von Dr. med. Henrik Egedal. Paper Price 2.80 marks Pp 86 Vienna & Leipzig Wilhelm Braumüller, 1933.

This is one of those critical writings on psychoanalysis which cannot decide whether to appreciate or reject Freud's doctrine. The first chapter of the book consists of quotations of different authors' controversial opinions about psychoanalysis. After this the author has difficulty formulating his own opinion. Unlike many critics of psychoanalysis, the author, who obviously has been fascinated by this new field, shows a fair knowledge of psychoanalytic literature and quotes extensively from Freud's and also to some extent from Ferenczi's and Jones's writings. It is obvious that his knowledge of psychoanalysis is a theoretical book knowledge and is not based on clinical experience. Accordingly his criticisms are more of a deductive nature. What he can accept are mostly generalities, but he finds the more specific references to case histories or dream interpretations often fantastic and unacceptable. He gives great credit to Freud's general dynamic concept of neuroses but is skeptical regarding the correctness of detailed interpretations. He does not agree with the psychoanalyst's concept of the phenomenon of transference and is inclined to consider it as a deluded form of hypnotic sugges-

tion. The reader cannot help but feel that the author is in the process of his struggle with this new approach and that the book is the result of this struggle to digest and understand it. His undecided ("ambivalent") attitude is expressed in the subtitle of the book, "an erroneous doctrine with an ingenious nucleus" and he ends his writing with the following statements:

He [Freud] dared to introduce into the psychology and psychiatric sciences the finely shaded thinking of the Russian and French belles lettres of the second half of the nineteenth century with this method he broke through the solid barriers of the limited physicochemical way of thinking in these sciences.

Art always anticipates sciences. Dostojewski, Ibsen and Maupassant ought to have waited many hundred years before they could express logically and inductively the psychological motivations of the heroes of their novels. Any one who like Freud had dared to make the courageous step of introducing into the psychological sciences ideas which can only be intuitively grasped but not proved was necessarily bound to go beyond the goal. It would be a misjudgment of the genius of the man if one only considered the defects of his accomplishments and not its merits.

The Anatomy of Surgical Approaches By L. C. Kellogg, A.B. M.D. Professor of Anatomy, College of Medical Evangelists, Loma Linda and Los Angeles, California. Cloth Price \$1.50 Pp 134 with 29 illustrations. Baltimore: William Wood & Company 1934.

This is a pocket size volume the chief purpose of which is to outline the specific methods of approaching the various structures within the body by means of external landmarks. Especial emphasis is placed on the extremities. No consideration is given to internal organs. The book is divided into four parts. The first deals with the upper extremity and considers the means of exposure of its arteries, nerves, bones, joints and tendons, as well as the spaces of the hand, palm and wrist. The second part considers the head and neck, giving special attention to isolation of the large vessels of the neck, the phrenic nerve and the technic of such procedures as incision of the maxillary nerve, exposure of the brachial plexus, and tracheotomy. The section devoted to the thorax and abdomen considers paracentesis pericardii, ligation of the internal mammary and iliac arteries, and the muscle splitting incision of the abdominal wall. The fourth part, like the first, deals with the exposure of the vessels, nerves, bones and joints of the lower extremity. The work is written well, simply and concisely. The directions are clear and easily followed. The book should prove of value to the surgeon, to the general practitioner who is at times called on to do surgery, and to the medical student.

Traité élémentaire d'exploration clinique médicale [technique et séméiologie] Publié sous la direction de Emile Sergent, professeur à la Faculté de médecine de Paris. Avec la collaboration de MM. Francis Bordet, Paul George, Hazard, d'Heucqueville, Camille Lian, René Mignot, Oury, Pierre Pruvost, Ribadeau Dumas et Emile Sergent. Cloth Price 145 francs Pp 1,176 with 420 illustrations. Paris: Masson & Cie 1934.

This is a complete and thorough book on medical technic. It is so complete that it is rather difficult to pick out any single phase of it for special comment. Almost all fields of diagnostic endeavor are covered and well covered. The section on x-rays contains some of the best printed roentgenograms we have ever seen. The rest of the illustrations are likewise excellent and to the point. The colored prints are as well done as one sees in special books devoted to the blood. The French seems easy to grasp. The book should be a standard reference book for clinical-technical procedures.

A Text Book of Medical Psychology By Ernst Kretschmer, Dr. Med. Professor of Neurology and Psychiatry in the University of Marburg. Translated from the fourth German edition with an introduction by E. B. Strauss, M.A. D.M. M.R.C.P. Assistant Physician to the Cassel Hospital for Functional Nervous Disorders. Cloth Price \$5 Pp 274, with 24 illustrations. New York & London: Oxford University Press 1934.

Here there is neither probing of metaphysical mysteries nor tracing of psychophysical intricacies. Any medical student or practitioner could read this book with profit, and every neuro-psychiatrist should. "Typological psychology" is given simply a fair share of prominence. A scant dozen pages are devoted to the research most readily associated with the author's name, that on the psychosomatic and other types of habitus with their associated temperaments. The experimental work of Enke, Kroh, Klages and investigators along similar lines is mentioned with approval. Decision is reserved on the more speculative conclusions of the Jaensch school—as generally in America. Exceptions have been taken to Kretschmer's types as being too

inflexible or mutually exclusive. He seems to meet such objections satisfactorily (p 147) with his description of "diathetic" and "psyaesthetic" scales, and his disclaimer "essential factors should not be artificially separated out by means of too sharply limited concepts." The subject of intelligence is handled in the best modern manner, against a sociological background. Consciousness and the degrees of the unconscious are discussed in terms of a less familiar concept, the 'sphaera.' Freud is given every credit for the epoch-making work of his school, the supreme importance of sexuality and of infantile traumas, however, is discounted. Jung fares best of the psychoanalysts. Kretschmer's "psychobiogram" has been criticized for its length and complexity. It is an excellent example of Teutonic thoroughness. In actual practice, not all the data would be obtainable in every case. The translation is thoroughly readable, the bibliography is well selected, and the index helpful.

Investigaciones sobre la enfermedad de Chagas. I. Sobre nódulos de histiocitosis en el hígado de perro inoculado con *S. cruzi*. Chagas de origen humano. Por los Doctores Salvador Mazza y M. E. Jörg. The eight papers in these publications appeared under the auspices of the University of Buenos Aires and form a valuable addition to the rapidly growing literature on Chagas disease, or American trypanosomiasis of man. Five papers give interesting clinical reports of cases occurring in Argentina: two deal with dogs and cats naturally infected with *Trypanosoma cruzi*, and one is a study of the histiocytic response in the liver of an experimentally infected dog.

The eight papers in these publications appeared under the auspices of the University of Buenos Aires and form a valuable addition to the rapidly growing literature on Chagas disease, or American trypanosomiasis of man. Five papers give interesting clinical reports of cases occurring in Argentina: two deal with dogs and cats naturally infected with *Trypanosoma cruzi*, and one is a study of the histiocytic response in the liver of an experimentally infected dog.

Tumors of the Female Pelvic Organs. By Joe Vincent Meigs. A.B. M.D. F.A.C.S. Instructor in Surgery. Harvard Medical School. With a foreword by Robert B. Greenough. M.D. President Elect of the American College of Surgeons. 1933. 1934. Cloth. Price \$6. Pp. 533 with 261 illustrations. New York. Macmillan Company. 1934.

In this book the author admirably describes the benign and malignant tumors affecting the pelvic organs and outlines the adequate treatment for each type. He has incorporated the most generally accepted views concerning these growths and has supported them by series of cases from the Massachusetts General Hospital. The text is ably written and affords a complete picture of each group. It is printed in large, clear type and on good paper. The illustrations amply supplement the text, are well chosen and appear chiefly in halftones and black and white. The chapter on carcinoma of the cervix is especially well written, as is the last chapter, on metastases. The author's discussion of total versus supravaginal hysterectomy for fibroids is rational and warrants the serious consideration of gynecologists and general surgeons alike. In estimating the significance of the retained cervical stump after supravaginal hysterectomy, Meigs found that in the Massachusetts General Hospital 'cancer of the cervical stump developed less frequently in patients who have had the top of the uterus removed than did cancer of the cervix in the group of women in the hospital as a whole. From this he deduces that total hysterectomy for fibroids as advocated by some physicians as a routine is not always warranted and that it would endanger the lives of some women who would probably never develop cancer. Periodic examination of the stump is advocated as even the unin-

jured cervix may develop cancer. Not only the surgeon but the radiation therapist and pathologist as well will profit by a careful study of this splendid book. Numerous references accompany each chapter. An adequate index is appended.

Técnicas de laboratorio. Análisis de alimentos. Análisis clínicos. Por Casaderante y Sanfella. Paper. Price 25 pesetas. Pp. 431 with 56 illustrations. Madrid. Javier Morata. 1933.

The first part of this book deals with the chemistry of sugars, fats and condiments, only the more elementary facts are stated. The second part is a laboratory manual, it gives many of the routine procedures for the more important laboratory examinations of urine, feces, blood, cerebrospinal fluid and sputum. There are several omissions and errors for example, a statement to the effect that "*Amoeba coli*" is the specific agent in amebic dysentery. The Wassermann test is given as the method of choice in the laboratory diagnosis of syphilis, but the precipitation reactions of Meimcke, Kahn and Sachs-Georgi are considered reliable. The microscopic agglutination test for the typhoid bacillus, paratyphoid bacilli and *Brucella melitensis* is recognized as the most satisfactory. The usual methods for the demonstration of tubercle bacilli in sputum are given. The only method for the detection of other pathogenic bacteria (pneumococci, streptococci and similar organisms) is the preparation of gram-stained smears.

Mental Health. Past, Present and Future. By Arthur Hiler Buggles. M.D. Superintendent of Butler Hospital. Providence, R. I. The Colver Lectures 1932. Published for Brown University. Providence, R. I. Cloth. Price \$1.50. Pp. 104. Baltimore. Williams & Williams Company. 1934.

The Colver Lecture in Brown University for 1932 primarily is a brief historical review of the development of psychiatry and of the growth of facilities for the care of the insane. Under three divisions, mental health of the past, of the present and of the future beginning with the time of Hippocrates, the changing conceptions of mental ill health are traced to the present time and the author's conception of the future development of psychiatry is sketched. The growth of hospitals for the care of the insane is particularly stressed. This brief work is exceptionally comprehensive in scope. In commenting on the multiplicity of factors that are pertinent to an understanding of conduct, the author has made it difficult for the layman to keep the thread of his discourse as it pertains to the problem of mental health. He has attempted to outline the concept that man must be understood not as a series of organs or a collection of diseases but rather as a total human being with his physical and mental equipment intricately interrelated. He has, however, not achieved an effective unity in presenting this theme. This is due to lack of selection and discrimination in emphasis. Encephalography as a diagnostic method and the social and emotional factors in schizophrenia are discussed in one and the same paragraph. This is too telescoped for the lay mind to deal with. The book is provocative rather than informative, the historical material is authoritative and the most interesting section is that dealing with the activities of Dorothy Dix and the establishment of the Butler Hospital, of which the author is at present superintendent.

A Synopsis of Regional Anatomy. By T. B. Johnston. M.B. Ch.B. Professor of Anatomy. University of London. Guy's Hospital Medical School. Third edition. Cloth. Price, 12s. 6d. Pp. 460 with 11 illustrations. London. J. & A. Churchill, Ltd. 1934.

This book is intended to help students engaged in a review of gross anatomy. Its arrangement is regional. It attempts to indicate the anatomic facts in each region that are practically important in surgery or medicine or that might easily escape notice. Students in our medical schools often state that they would like to know which facts in anatomy are of the most importance in actual clinical work. They will find in this book a reliable indication. It is not lengthy, the author has selected the points to which attention is given wisely and has stated them clearly. It would find its greatest usefulness if read in connection with a review study of a dissected part or of a skeleton. Study of dissections after their completion would be of more value to the students of anatomy than many of them realize and in such a study this book would be of great help. It can be recommended to students reviewing gross anatomy in connection with the study of surgery.

Medicolegal

Insurance, Life "Due Proof" of Total and Permanent Disability—The New York Life Insurance Company issued to the plaintiff an insurance policy providing for the payment of certain benefits on receipt of "due proof" that the insured has become wholly disabled by bodily injury or disease so that he is and will be presumably thereby permanently and continuously prevented from engaging in any occupation whatsoever for remuneration or profit. The plaintiff, 40 years old, became afflicted with phlebitis and a blood clot formed in the vein, in the thigh of his right leg. Contending that he was totally and permanently disabled, he applied for the benefits payable under the policy. The insurance company denied liability. In a suit to collect the benefits the trial court gave judgment for the plaintiff and the defendant appealed to the Supreme Court of Michigan.

The medical testimony, said the Supreme Court, established the fact that the plaintiff could not pursue any suggested vocation with a reasonable degree of regularity or length of time and without hazard of relapse. The physicians who attended the insured stated that he was not able to engage in any occupation for gain except under circumstances so favorable and fortuitous as to be without the range of probabilities. They testified that the insured's disability was probably permanent. The insurance company contended, however, that "due proof" of total disability had not been submitted to it, as required by the policy. Of course, said the Supreme Court, the policy cannot fairly be construed to constitute the defendant insurance company the sole judge of disability or to mean that the fact of permanent disability is foreclosed in favor of or against either party by the proof made to the company by the insured. Actionable disability ultimately, said the court, is a question of fact for trial. "Due proof" can mean no more than that reasonable evidence of disability within the terms of the policy shall be submitted to the company. Where such evidence is submitted in a good faith attempt to comply with the provisions of the policy, the company should point out particularly any defects therein if it intends to rely on them. The insured in this case submitted the reports of four attending physicians covering treatments from July 26, 1928, to June 1930, showing the character of his ailment and that he was totally disabled continuously during that time. The physicians who early treated him made a prognosis that his disability would extend into the future but did not then express an opinion that it would be permanent. However, they became progressively doubtful of his recovery as time passed and the condition did not yield to treatment. The physician who attended him in 1930 stated "It is my opinion that as much collateral circulation has been established in the Rt leg as is possible and that condition now is one of total and permanent disability as far as pursuing occupation is concerned." Having before it proof of the nature of the disease, concluded the Supreme Court of the results of treatment for two years, of the fact of past and present total disability, and medical opinion that it would be permanent, the defendant insurance company had such reasonable showing of total disability as constituted "due proof" and required it to pay the benefits or to be prepared to defend on the fact of disability. The judgment in favor of the insured was consequently affirmed.—*Forman v New York Life Ins Co (Mich)*, 255 N W 222.

Foods Liability for Death from Trichinosis—The plaintiff, as administrator of the estate of his deceased wife, brought this action against a retail dealer in meats and against the defendant packer claiming that his wife contracted trichinosis as a result of the ingestion of uncooked sausage prepared from raw pork containing trichinae, purchased from the retail dealer, who in turn obtained it from the packer. The retail dealer was relieved from liability by a directed verdict, and a verdict was rendered against the packer, from which an appeal was taken to the Supreme Court of Michigan.

The testimony showed said the Supreme Court that there is no known, practicable or feasible method of determining whether hogs are infected with trichinae. The bacteria can be detected only by microscopic inspection of the entire carcass of the animal although the organism is generally found in the

muscles. Until 1906 it was the practice of the government to make such examinations, but this practice was finally discontinued because it was found to be ineffective. The only known treatments generally effective in killing trichinae are (1) freezing for twenty days at a temperature not higher than 5 degrees Fahrenheit, (2) raising the temperature of the meat to 170 degrees momentarily, or (3) a prescribed curing process. All of these processes, although effective, remove from the meat in a degree the quality of freshness demanded by the public. None of these methods were used by the packer in the preparation of fresh pork but the evidence clearly showed, continued the court, that all the ordinary, usual and reasonable precautions taken by the meat packing industry were observed in the present case. There was no testimony revealing any negligence on the part of the packer. There was no breach of duty chargeable to it. The fresh pork was prepared by the methods adopted by other packers engaged in similar businesses. The methods of preparation and inspection measured up to the standard demanded by the federal government.

A Michigan statute forbids the sale of adulterated foods, including diseased or tainted meats. The plaintiff contended that a violation of this statute was negligence per se. To give the statute such force, said the court, would in effect impose on the packer the liability of an insurer, regardless of the unusual nature of the use to which the product is put. The legislature did not intend to impose on the producer the absolute civil responsibility of an insurer in cases in which every reasonable means designed to guarantee the safety of food for normal use has been employed. Likewise it would be manifestly unfair to impose the liability of an insurer on the meat packer through the implication of a warranty that pork is fit for human consumption in a raw state. This is especially true in view of the fact that the danger of infection can be reduced almost to the vanishing point by ordinary cooking methods. Fresh pork is not ordinarily intended to be eaten raw. The warranty should be applied only to food used in the usual rather than in the unusual and improper manner. The court was satisfied that the packer could not be held liable either for negligence or for breach of implied warranty and therefore reversed the verdict of the jury in favor of the plaintiff.—*Cheli v Cudahy Bros Co (Mich)*, 255 N W 414.

Corporate Practice of Optometry Illegal—Harris and others, the relators in the present case, presented to the secretary of state of Ohio articles of incorporation wherein they sought to incorporate the Columbus Optometric Company to engage "in the business of the practice of optometry." The secretary of state refused to accept the application on the ground that "the purpose clause of such articles of incorporation discloses that such corporation is attempted to be formed for the purpose of practicing a profession" in violation of section 8623 3, General Code of Ohio, which prohibits incorporation for profit for the purpose of carrying on the practice of any profession. The relators then sought a mandamus to compel the secretary of state to file the proffered articles of incorporation.

Whatever refinements of reasoning, said the Supreme Court of Ohio, may be brought to bear on the question of whether optometry is a business to be carried on or engaged in or a profession to be practiced, the legislature has definitely placed it in the category of professions. The Ohio law regulating optometry makes it unlawful for any person to practice optometry who is not more than 21 years of age and who has not met the requirements prescribed in the law. Evidence of preliminary education must be furnished and a two year course in optometry completed. The qualifications of the applicant are to be tested by an examination conducted by a board appointed as provided in the law. Not only is good moral character made one of the prerequisites to admission to the examination but the board is authorized to revoke a license for any of the causes enumerated, among which are gross immorality, grossly unprofessional or dishonest conduct. Throughout these statutory provisions the court said the legislature has recognized optometry as a profession. It thus appears, concluded the court, that the secretary of state has not refused to perform a duty enjoined on him by law for which mandamus would lie but that on the contrary, in his refusal to accept and file the proposed articles of incorporation

he has acted in obedience to the requirements of section 8623-3, General Code of Ohio. The petition for a writ of mandamus was therefore denied—*State ex rel Harris et al v Myers, Secretary of State (Ohio), 191 N E 99*

Workmen's Compensation Acts Rupture of Artery Attributed to Overexertion—The employee was engaged in pulling a heavily loaded truck, with the assistance of others, up an incline. As a result of the strain incident to the work, it was contended that an artery in his right leg was ruptured and that as a result of this rupture a thrombus developed which lodged in the lower right lung, causing death. The industrial commission awarded compensation to his widow. The circuit court confirmed that award and the plaintiff appealed to the Supreme Court of Wisconsin.

The employee was afflicted with arteriosclerosis in an advanced degree, which condition, said the Supreme Court of Wisconsin, rendered him liable to just such a result as did occur. To a man in his condition, the risk of serious illness or death was increased by unusual exertion. The evidence in the case, continued the court, left no doubt that the artery was extremely brittle and that the rupture was caused by less pressure or exertion than would have been required to cause it in a person of normal condition. This fact, however, did not prevent the rupture from being the result of the employee's work. While compensation, said the court, was not intended to take the place of life insurance, a showing of a fortuitous circumstance happening in the prosecution of one's work and having an open and direct relation to the industry causing injury brings the case within the workmen's compensation act of Wisconsin. The word "accident," as used in workmen's compensation cases, continued the court, includes ruptures resulting from lifting heavy objects. The very serious condition of the employee, warranting a belief that his death was likely to follow almost any exertion, makes this a doubtful case, said the court, but it cannot be said that there was no credible evidence to sustain the finding of the commission that the rupture was caused by the pulling of a heavily loaded truck up a short incline and that this exertion was the cause of the subsequent death. The judgment confirming the award was affirmed—*Malleable Iron Range Co V Industrial Commission (Wis), 255 N W 123*

Workmen's Compensation Acts Postponement of Herniotomy as Affecting Compensation—The employee May 15, 1924, sustained a double hernia in the course of his employment. A claim for compensation was filed with the department of labor and industries and the employee was notified that he would be required to undergo an operation and make report thereof to the department. In September, the operation not having been performed, the department, without notice to the employee, suspended the claim for compensation. Until March 1933, nothing further happened with respect to the matter. On March 2, 1933, approximately nine years after the accident, the employee was operated on for hernia, without the knowledge of, or any renewed authority from, the department, and a claim for the expenses incident to the operation was filed with the department. The claim was rejected on the ground that the statute of limitations had run against it, and that therefore it could not be reopened for further consideration. The superior court agreed with the finding of the department, and the employee appealed to the Supreme Court of Washington.

The workmen's compensation act of Washington provides that if an employee "shall refuse to submit to such medical or surgical treatment as is reasonably essential to his recovery, the commission may reduce or suspend the compensation of such workman." It will be observed, said the Supreme Court, that the right of the department to reduce or suspend compensation arises out of the refusal of the workman to submit to medical or surgical treatment. The penalty for such refusal is not the denial of the claim in toto, but simply its reduction or suspension. The term "suspend" read in connection with its context, contemplates a temporary withholding of payment pending a submission to treatment, and does not in the absence of a wilful refusal to comply with a proper order, contemplate an absolute denial of the claim in its entirety. In this case the employee was never notified that his claim had been suspended. From aught that appears in the record the employee

was conscientiously attempting to get along without an operation and without claiming the benefits to which he was, at the time of his injury, admittedly entitled. Having been specifically told by the department that when the operation was performed the claim would go forward for payment, the employee was led to believe, in the absence of a contrary notice, that when the operation became necessary he might then have it performed. The only question for decision here, said the Supreme Court, is whether the order of suspension, without notice to the employee, canceled and terminated all right of compensation. We are clearly of the opinion, concluded the court, that, under the facts in the case, it did not. The judgment of the superior court was therefore reversed with instructions to remand the case to the department with directions to award compensation.—*Urquhart v Department of Labor and Industries (Wash), 33 P (2d) 380*

Paint Poisoning, Death from Septicemia, and Workmen's Compensation—Lockhart, a shop foreman, painted vehicles with a "spray gun," as a part of his employment, when there were no painters available. While so painting April 17, 1932, he was taken sick and symptoms of paint poisoning developed. His body became covered with a rash, he developed an elevation of temperature, and suffered from nausea and cramps. Under medical treatment, he was recovering from the effects of the paint poisoning, when, about the middle of May, a localized infection developed in his ankle. Septicemia ensued and Lockhart died, June 20, 1932. The compensation commissioner declined to award compensation to the widow and she appealed to the Supreme Court of Appeals of West Virginia.

The evidence tended to show that death resulted directly from the infection originating in the ankle. Had death been due directly to the paint poisoning, said the Supreme Court of Appeals, there would be little question as to the right of the widow to compensation, for the evidence showed that Lockhart contracted the paint poisoning following the specific exposure while painting, April 17. Notwithstanding the fact that the paint poisoning was not the direct cause of death, continued the court, the uncontradicted evidence made out a prima facie case of compensability. From the evidence, it is clear that Lockhart would not have died, and indeed might not have suffered at all, from the infection that settled in his ankle had it not been for his weakened and debilitated condition directly traceable to the paint poisoning. The infection came before his complete recovery from the paint poisoning and its effects. There was, therefore, a clear preponderance of evidence establishing a direct causal connection between the paint poisoning and the death. The order of the compensation commissioner, refusing to award compensation, was therefore reversed and the case remanded for further consideration.—*Lockhart v State Compensation Commissioner (W Va), 174 S E 780*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Position of Heart Valves and Relation to Chest Wall—Sosman and Wosika draw the following deductions with regard to the position of the aortic and mitral valves in patients with abnormal hearts. 1 Both valves are likely to be found on a line 45 degrees from the horizontal, starting at the auriculo-ventricular groove on the left border of the cardiac shadow, this line corresponding to the position of the auriculoventricular groove. 2 The mitral valve is likely to be more to the left of the midline than the aortic valve, and the latter may be exactly in the midline. 3 The aortic valve usually is more caudad than the mitral valve in relation to the wall of the chest, but it may be more cephalad in relation to the total bulk of the cardiac shadow. This is probably due to the predominance of the left ventricle in aortic disease and to the large dilated auricles in mitral disease. 4 In the right anterior oblique position the two valves may occupy the same position in relation to the cardiac outline. 5 The left anterior oblique view is the best for differentiating between aortic and mitral valve calcifications. Small areas of calcifications visible in the other oblique view may not be visible in this view. If large enough to be seen in the left anterior-oblique position, the mitral valve calcifications will be found to lie in the posterior third of the cardiac shadow, while the aortic valve calcifications are usually in the middle third. If the posterior cusp of the mitral valve is calcified, it may be within 1 cm from the posterior surface of the heart shadow. 6 In calcified annulus fibrosis cases the shadows are likely to be larger and denser and on the roentgenograms are more homogeneous in appearance than the irregularly mottled calcifications in the mitral leaflets. They occur frequently in patients without discoverable heart disease and are usually found in patients 60 years of age or older. 7 If both valves are calcified they may move independently, i. e. their dancing excursions with the beat of the heart are not synchronous but consecutive.

Factors Concerned in Cardiac Hypertrophy—Willius and Smith observed that the greatest average cardiac weight occurred in cases of aortic stenosis. In order of cardiac weight, other lesions occurred in the following sequence: aortic insufficiency,

multiple valvular lesions, mitral stenosis and insufficiency, and pure mitral insufficiency. There was a marked correlation between the degree of the lesion and the average weight of the heart. There was a suggestive correlation, evidenced only in some groups, between the average weight of the heart and the interval elapsing from the initial attack of rheumatic fever to death. The condition of four children, who lived only for a short time following their first illness with rheumatic fever and chorea in one case, and three of whom had rather slight valvular defects, strongly suggests that myocardial injury by infection or its toxins in some instances permits the heart to respond by hypertrophy. Although increased cardiac work imposed by the valvular defect or defects appears to be the principal influence in the production of cardiac hypertrophy in rheumatic heart disease, other factors appear to exert a definite but less important influence. Among them is the length of time the heart is subjected to the lesion and actual myocardial injury in a certain group of cases.

Total Thyroidectomy in Angina Pectoris—Shambaugh and Cutler believe that the resulting lowered metabolism with slowing of the circulation and consequent lessening of the burden on the heart produced by total thyroidectomy in angina pectoris cannot be the entire explanation, in that a beneficial effect has been observed almost immediately after operation, whereas the basal metabolic rate does not begin to fall for over a week. Their experiments on dogs suggest that the early and dramatic change may be due to a change in reaction to epinephrine after operation. They studied the effect of thyroidectomy on the vasopressor action of epinephrine in dogs and found a definitely diminished response in two dogs when tested three and four weeks after thyroidectomy. Three other dogs tested one, two and six weeks after thyroidectomy failed to show this change. The individual variation in this regard may be due to the presence of varying amounts of accessory thyroid tissue. The beneficial effect of the removal of the thyroid in angina pectoris may be due, in part at least, to a diminished effectiveness of the physiologic output of epinephrine. This explanation would imply that the paroxysms of anginal pain in patients with coronary artery disease may be caused by an increase from time to time in the patient's output of epinephrine. Such a concept does not seem entirely unreasonable when it is known that the physical and emotional changes which precipitate attacks of angina are just those which have been shown experimentally to cause an outpouring of epinephrine into the blood stream. It has been demonstrated that injected epinephrine will generally initiate an attack in patients suffering from angina pectoris so it is quite conceivable that a sudden increase in the secretory activity of the suprarenals might have a similar effect in these patients. Epinephrine, either secreted or injected might precipitate an attack of angina by causing a constriction of the coronary arteries which would directly produce the myocardial ischemia or by raising the blood pressure and heart rate, it may so increase the vascular demands of the myocardium that in the presence of a preexisting narrowing of the coronary artery or of a rigidity preventing a compensatory dilatation it causes a relative myocardial ischemia.

Interlobar Effusions in Heart Disease—Stein and Schwedel review the clinical course of eighteen cases presenting interlobar effusions and stress the comparative frequency with which the condition is encountered and its relationship to the general problem of myocardial insufficiency. In nearly all the cases studied the effusion was on the right side. Physical signs are comparatively few and the condition is usually an accidental observation in the teleroentgenogram. Verification by puncture is unsatisfactory. Their rapid disappearance with treatment is characteristic and refutes the common conception that diuretic measures are of no avail in the mobilization of chest fluid. This may be true of the ordinary type of hydrothorax but it does not apply to interlobar fluid. The difference between the two probably lies in the fact that the total fluid area involved is much less, and that the two areas of lung tissue which bound the fissure form a more active resorption surface. The relationship of auricular fibrillation and diseases of the aortic valve to this condition has been stressed by Vessell and Austrian. The authors feel that these are coincidental and are merely expressions of long standing cardiac disease associated with decompensation. Differentially, lung abscesses, tumor nodules or

pulmonary infarcts may closely resemble interlobar effusions, and confusing shadows may be cast by the pectoralis and trapezius muscles, or by localized thickening of the pleura in the general pleural cavity. A density of this sort in a decompensated person, which seems to melt away with the return of compensation, should present no great diagnostic problem.

Carcinoid Tumors of the Small Intestine—In 3,200 necropsies, Humphreys found three examples of carcinoid tumors with metastases in regional lymph nodes. Two of these were multiple carcinoids, one with two the other with nine independent tumors. In two the lumen of the intestine was narrowed. In the same series there were five solitary carcinoid tumors without metastases, one in the jejunum, three in the ileum and one a carcinoid polyp of the rectum. Thus in this series of necropsies the incidence of all carcinoids was 0.25 per cent, for carcinoids of the small intestine 0.22 per cent, for multiple carcinoids, 0.06 per cent, and for metastasizing carcinoids, 0.09 per cent. It is evident that the carcinoid tumor of the small intestine is far from a harmless lesion.

Malignancy and Rate of Growth of Tar Warts—While studying individual warts following prolonged tarring of the skin of mice, Mottram observed a close correlation between malignancy and the high rate of growth. A few warts appear within 100 days after the beginning of tarring, the majority between 100 and 150 days and few after 300 days. The time of appearance of benign warts and of warts which disappear is not different, but malignant warts appear somewhat later. Fast growing warts do not appear earlier than slow growing, but later. Warts when first seen are for the most part sessile, a few are pedunculated. A small proportion of warts are ulcerated when first seen and begin as sores; many of these are then malignant. Many warts at first sessile later become pedunculated. Pedunculated warts are almost always benign, as are also horny warts, whereas warts that remain sessile are largely malignant. The lateral and deep extension of warts observed during life is not a completely reliable sign of a malignant manifestation since infective conditions lead to exactly similar signs on palpation. The length of life of warts that disappeared varied from four to 190 days. The height of warts was found to be variable. Sometimes a sudden increase in growth was observed and in all these cases the wart was then found to be malignant. The majority of benign warts have a low growth rate, while malignant warts have a high rate. There is a close association between ulceration and malignancy. Many warts are malignant only locally, since both epitheliomas and simple epithelial cysts resulted from the inoculation of different fragments of the same wart. Benign warts likewise vary from fragment to fragment. Autografts give rise to semi-malignant epithelial cysts and thus show that warts form a continuous series from malignant, through semimalignant, to benign. The whole wart should be divided in fragments and all the fragments inoculated in order to exclude malignant changes. The author reviews the problem of cancer.

Why Cancer Is Not Recognized Early—MacCarty selected at random 100 cancers of the stomach removed surgically. Throughout the 100 clinical histories one finds such terms or expressions as pain (dull or sharp, sudden or burning), weakness, tired feeling, nausea, vomiting, flatulence, bloating, sour eructations, feeling of fullness, indigestion, stomach trouble

and periodicity of symptoms. Reports of the physical examination, contrary to the classic descriptions in textbooks, show absence of such features as emaciation, palpable tumor in the epigastrium, anasarca, accessory nodules, cachexia, pallor, edema of the legs, hematemesis, tarry stools and loss of weight greater than might be explained by a restricted diet. Strangely, also, gastric acidity was high rather than low, and the hemoglobin records were normal in the great majority of cases. None of these signs, symptoms or laboratory observations are pathognomonic of cancer. All may be found when no cancer is present as in simple gastric ulcer, duodenal ulcer and, frequently, in association with cholecystitis and even appendicitis. Such symptoms are common in any group of Americans, and certainly not all of these have cancer. It is fair to suspect, however, that some may have cancer, and this cannot be determined by signs and symptoms alone. As long as physicians continue to wait for the textbook picture of cancer they will continue to find a high proportion of hopeless cases. Cancer does occur as a small lesion. As such, its signs and symptoms are not those described for cancer in the textbooks of pathology and of the practice of medicine. Cancers are not recognized early and never will be until physicians learn that there are no characteristic signs and symptoms for early cancer and that the only means of telling whether the condition is gastric, duodenal, appendical or in the gallbladder is by the x-rays. It makes little difference for the present whether pathologists believe that cancer can be diagnosed from cells alone or not. The risk of cancer is still greater than the risk of removing a few benign ulcers, which may be cancer so far as signs, symptoms, roentgen data and gross appearance are concerned.

Treatment of Cancer of Pharynx by External Irradiation—Martin and McNattin describe the treatment of 140 cases of cancer of the pharynx, tonsil and extrinsic larynx by divided doses of external radiation. The first requisite is the careful localization of the tumor by indirect mirror examination. For the examination of the posterior nasopharynx, the soft palate retractor is used. A biopsy is taken at the time of the first examination. With the aid of the palpating finger, the exact situation of the underlying tumor is marked on the skin of the neck by a dye. The relationship of any metastasis is then determined so that the skin portal will amply include both primary growth and metastasis. The size and shape of the skin portal, the direction of the beam and the daily dose are then decided on. At present, the period of treatment is about twenty days, it and the total dose being extended if the clinical course and local and general tolerance so indicate. With portals of from 7 to 10 cm. in diameter, treatment is begun with from 350 to 400 roentgens (measured in air) daily to alternate sides of the neck, so that at the end of twenty treatments the patient has received from 3,500 to 4,000 roentgens to each side. The patients are examined daily and any variations from the

technic originally decided on will depend on the clinical course. At the end of from fifteen to twenty days in some cases it will be found that less than the expected reaction has occurred in both normal and neoplastic tissues. In such cases the daily dose may be raised or the treatment continued beyond the period of twenty days. In cases in which the reaction is unusually early and marked, accompanied by rapid regression of the tumor, the daily dose may be lowered or treatment discontinued before the original plan is completed. In most cases it is best to err on the side of heavy treatment, since a marked reaction is usually followed by prompt healing and excellent regression of the tumor. The authors see no advantage in interrupting the treatment so as to give the patient a rest of several days before completing the original plan as is recommended in some cases by Coutard. When unusually severe reactions develop or in the case of a surgical complication such as tracheotomy, the daily sequence of treatments must be temporarily discontinued. If only one portal is used, the authors ordinarily give treatments on alternate days as a matter of convenience. Of 140 cases treated during 1931 and 1932 there remained forty-one free from disease in September 1933.

Radium Dosage in Carcinoma of Breast—Taylor used interstitial radium treatment in forty selected cases of inoperable carcinoma of the breast. Keynes platinum needles have been employed with doses ranging from 5,000 to 20,000 mg. hours. Roentgen treatment has been given in addition to radium in most cases. Regression of the local process was secured by treatment in almost all cases and seemed to be better than that which could be secured with roentgen treatment alone. Of the forty patients treated, nineteen are dead. Two of these had favorable regressions of the lesion and died of other causes five months and two years after radium treatment. One lesion proved on pathologic examination to be a gumma rather than carcinoma. Of the twenty remaining cases, eight were treated within six months and are too recent to permit judgment of the effect of treatment. One of the remaining twelve patients was subjected to radical operation six months after the radium treatment and now shows no evidence of disease one year after operation. The remaining eleven cases all present evidence of uncontrolled metastatic disease: nine in the axillary and supraclavicular areas and four in the skeletal system. As regards the immediate effect of the radium treatment, thirty-seven of the cases showed regression of the primary breast lesion, and this has been apparently a permanent arrest in twenty-four cases. Three patients showed no regression of the local process after radium treatment and died rather rapidly. Axillary metastases showed regression after radium treatment in fourteen cases. This was rarely so complete or so lasting as it was in the case of the primary breast lesions. In only five cases was regression observed in nodes in the supraclavicular region. No effect was observed on the propensity to develop remote metastases.

Calcification in Intestinal Tuberculosis—Heacock points out that calcification is the rule in old tuberculous foci, whereas in other types of infection it is the exception. The most common site for calcareous deposits in tuberculous foci is the lymph nodes, the lungs are second, and the third most common location is probably in the kidneys. Apparently, calcification also occurs in primary lesions of intestinal tuberculosis. The author examined five patients with scattered milary areas of calcification, apparently in the walls of the cecum. These five cases are reported. The mere presence of calcification in these cases was not interpreted as definite indication of healing or even of the presence of the disease itself. The routine examination of the gastro-intestinal tract was carried out with special regard to the accepted technic to discover intestinal tuberculosis. In all the cases the roentgen signs of the disease were present. The possibility that these shadows might be small flecks of ingested opaque material was eliminated by a second examination and the finding that the shadows were constant in size, contour and position. Calcified abdominal glands possess a different appearance. Although they may be mottled, lime salts occur in collections which outline the contour of the gland. Injections of bismuth and mercury compounds and salts of other metals into the buttocks will sometimes leave an opaque residue which is not absorbed. Shadows thus produced however are also in clusters and are not made up of multiple milary

shadows. The clinical history will prevent their being confused with those of tuberculosis. The author does not agree with Stumbach that the signs usually considered diagnostic of intestinal tuberculosis are highly unreliable in more than 52 per cent of cases. The demonstration of calcium, which is possible only by the use of the x-rays, will probably be of the highest value in an estimation of the extent of healing and of benefit of treatment.

Nonpainful Features of Coronary Occlusion—White points out that an appraisal of the nonpainful features is necessary if accurate diagnosis is to be made in coronary occlusion and if further steps are to be taken in determining during life whether actual necrosis of a considerable or important part of the wall of the heart has occurred. Fever and leukocytosis are signs of infarction whenever this process occurs in any considerable amount anywhere in the body. In coronary thrombosis, the blood pressure is nearly always lowered as compared to previous levels. The pericarditis that develops following coronary infarction is seldom accompanied by demonstrable effusion. Intracardiac thrombosis occurs when the infarction reaches the endocardium. The occurrence is signaled in life only by embolic phenomena. Changes seen in the electrocardiogram vary from striking to changes that are minor and indeterminate. Pre-cordial pain alone is not adequate for the diagnosis of cardiac infarction. Given a patient seized with typical precordial pain if there is an area of infarction large enough to give fever, leukocytosis, pericarditis, intracardiac thrombosis or considerable changes in the ventricular complexes of the electrocardiogram a long period of rest is advisable to promote firm scarring of the area. A minimum of eight weeks is advised. If the signs of infarction are lacking, less drastic restrictions are in order and the diagnosis may be in question. Pain alone, regardless of how typical its character seems to be, is inadequate for an

accurate and final diagnosis. Rheumatic carditis, pulmonary embolism, disease of the gallbladder and other lesions of the upper portion of the abdomen, and rupture of the aorta with interstitial hematoma present particular difficulties in differentiation. Coronary occlusion may occur without pain and cause gross infarction. Study of the nonpainful features gives the only clues to the diagnosis. Two of the many changes in rate and rhythm, i. e., ventricular tachycardia and heart block, are of particular importance in prognosis and treatment.

Glycogen Formation in Diabetes—Lukens states that there exists in the diabetic organism a marked capacity to maintain the muscle glycogen at about the same level as is found in fasted normal animals. He has made a comparison of the time relationships of glycogen resynthesis after exercise in normal and in diabetic animals, from which he concludes that (1) in the earlier phases of muscle glycogen recovery the diabetic animal is similar to the normal and (2) in the later stages, presumably involving the conversion of dextrose to muscle glycogen, the normal animal shows a more rapid resynthesis, although over a recovery period of twenty-four hours the degree of glycogen reformation is the same. The probability that this phase of carbohydrate metabolism is independent of the action of insulin and of the oxidation of carbohydrate is discussed.

Excretion of Mercury After Oral Administration—

The excretion of mercury, and presumably its absorption and effective concentration in the blood and the tissues in the case of the oral administration of 0.2 Gm of mercury with chalk daily and of 0.016 Gm of yellow mercurous iodide four times per day, were found by Sollmann and his associates to be nearly the same in degree and in course as those obtained with treatment byunctions, when 4 Gm of stronger mercurial ointment, containing 50 per cent of mercury, is used daily. These preparations may therefore be expected to give equivalent therapeutic effects. With the use of a dosage of 0.5 Gm of mercury of chalk daily, the excretion was twice as great as with the dosage of 0.2 Gm. On the basis of its content of mercury, the absorption of yellow mercurous iodide was about twice as great as that of mercury with chalk. The excretion of mercury with the use of 15 mg of corrosive mercuric chloride a day was between one-fourth and one-third that with the administration of 65 mg of yellow mercurous iodide daily; this difference corresponded closely to that in the content of mercury, but the excretion with this dosage of corrosive mercuric chloride was probably below the desirable therapeutic level. The amount of mercury excreted rose progressively with the continued administration of each of these preparations and declined rather slowly during the after-period, though more promptly than with the employment ofunctions. This cumulative effect is presumably due to the progressive coating with mercury of the intestinal mucosa, especially the surface of the villi which produces increasingly large depots for absorption.

Filamentous Change in Inflammations of the Scalp—Knowles and his co-workers state that certain hairs the roots of which exhibit threadlike wrappings can be found consistently in patients with neurodermatitis of the suboccipital region. In

glycerin preparations these filaments seem to follow the contour of the intercellular spaces of the cuticle or of the internal epithelial sheath. When treated with a solution of sodium hydroxide or potassium sulphide the swelling of the hair root tightens the filaments so that they may be mistaken for hyphae. The composition of the threadlike bands has not been determined. The authors believe that the filaments are in the nature of an intercellular exudate thrown out by the internal epithelial sheath as a result of the inflammatory process of the neurodermatitis. If the filaments are characteristic of neurodermatitis they constitute an aid in differential diagnosis.

Cutaneous Torulosis—Wile reports a case of fatal torulosis with cutaneous lesions differing somewhat from those described previously. Cutaneous manifestations of torulosis can occur as acneiform pustules, granuloma-like ulcers and deep-seated abscesses. To these must now be added subcutaneous and deep-seated nodules resembling ecchymoses varying in size from small plaques to those the size of a hand and having no tendency to ulceration. In histopathologic characteristics cutaneous torulosis conforms to that seen in other organs, modified only by the cutaneous structure. In general it may be described as a caseating, granulomatous process, characterized by enormous numbers of giant cells of the foreign body type, little inflammatory reaction and a peculiar form of caseation, which may lead to ulceration but did not in the present case. From blastomycosis the condition is easily differentiated pathologically by the absence of abscess formation and by the enormous numbers of organisms existing free and contained in giant cells throughout the section. From coccidioid granuloma it is differentiated not only by the same features that differentiate it from blastomycosis but also by the absence of endosporeulation. While few cases occur in the literature, it is suggested that cutaneous manifestations of *Torula* and indeed torulosis itself may not be so rare as the reported cases would seem to indicate.

Exchange of Lipids in Umbilical Circulation—Boyd and Wilson present evidence indicating that certain lipids are added to umbilical blood by the placenta and removed or absorbed by the fetus. Whole blood from the umbilical artery at birth contained 22 per cent less phospholipids and 14 per cent less free cholesterol than whole blood from the umbilical vein. Ester cholesterol was also lower in arterial blood but only when venous blood contained more than 10 mg per hundred cubic centimeters of this lipid. Neutral fat was lower in about half the cases and higher in the other half. The results were considered to signify that phospholipid and free cholesterol are regularly absorbed by the human fetus from umbilical blood at birth, ester cholesterol providing that there is sufficient (more than 10 mg per hundred cubic centimeters) to be absorbed while neutral fat may be either absorbed or given up. It was estimated that more than 40 Gm, 75 per cent of which is phospholipids, of these substances are absorbed in twenty-four hours by an average large, well nourished human fetus at birth. Whole blood which lies in the placenta between the time that the cord is clamped and the time that the placenta separates from the uterine wall was found to acquire additional amounts of phospholipids in twelve of fourteen cases, free cholesterol in three fourths of the cases ester cholesterol in two thirds and neutral fat in half of the cases. It was concluded that the placenta adds all of these substances to umbilical blood and may remove some of them, especially neutral fat. Phospholipids, free cholesterol and ester cholesterol therefore pass in general in one direction, namely from the placenta to the fetus, while neutral fat may pass in either direction. The composition of fatty acids in plasma from the umbilical vein were found similar, in respect to their iodine number to those of adult plasma except phospholipid fatty acids which are apparently more

saturated in the fetal circulation. It is probable that the fetus absorbs the more saturated phospholipid fatty acids and that it has an especial avidity for the cephalin fraction of the phospholipids. The white blood cells of fetal blood contain about half the lipid concentration of adult leukocytes, which is probably due to the greater proportion of lymphocytes in the blood of the fetus at birth. No evidence was obtained that they function in the transport of fat from the placenta to the fetus or vice versa.

Isolation of Coproporphyrin I from Urine in Cinchophen Cirrhosis—Watson isolated a porphyrin from the urine of a patient with cirrhosis of the liver, the latter probably caused by cinchophen. It has been identified by virtue of the ester melting point and spectroscopic character as coproporphyrin I. There was no suggestion in the behavior or appearance of the patient's erythrocytes, during life, of bone marrow irritation. There is little reason, therefore, to assume that this increase of coproporphyrin in the urine occurred because of increased formation in the marrow such as is the case in congenital porphyrinuria and pernicious anemia. Rather than derived from excessive formation in the marrow, it was believed that the porphyrin isolated was the normal coproporphyrin of the urine increased because of the damaged excretory power of the liver. Van den Bergh has recently discussed the retention of coproporphyrin in the blood serum in obstructive jaundice. He obtained experimental evidence to suggest that the coproporphyrin of the bile is formed in the liver. According to this, one would expect relatively large amounts of urinary coproporphyrin in simple obstructive jaundice, and smaller amounts or none in jaundice due to liver disease. This was apparently not true in the author's case, since there was advanced liver disease. The damage was fairly well limited to the periphery of the lobules and there was obviously a definite biliary obstruction. In three cases of common duct obstruction due to stone, the urine was found to contain definite but only moderate increases of coproporphyrin, much less in amount than in the case of cinchophen cirrhosis. Coproporphyrin or porphyrin was not isolated in the urine from a patient who later died of hepatic insufficiency due to advanced hepatic lobatum.

Porphyrin in Feces of Familial Hemolytic Jaundice—A heretofore undescribed porphyrin whose methyl ester melts at from 202 to 203 C, having some of the characteristics of a deuteroporphyrin but differing from the deuteroporphyrins spectroscopically, has been isolated by Watson from the feces in a typical case of familial hemolytic jaundice in which a hemolytic crisis was present at the time the feces were collected. This porphyrin occurred in association with a marked increase of coproporphyrin I. In four other cases of the same disease the excretion of coproporphyrin was moderately increased, and in two of these instances it was again isolated and shown to be coproporphyrin I. If this coproporphyrin is to be related to the protoporphyrin of the erythrocytes, as described by van den Bergh, the latter would have to correspond to etioporphyrin I. The possibility of independent formation in the marrow erythroblasts must also be considered.

Isolation of Coproporphyrin I from Feces in Untreated Cases of Pernicious Anemia—Watson has obtained coproporphyrin I also from the feces in two typical cases of pernicious anemia during relapse and has identified it by virtue of the ester melting point and absorption spectrum. In one of these, studied again after the liver had induced a remission the amount was obviously decreased and too small to isolate. In similar amounts of feces from two normal subjects and four having anemias of other types, the amounts were too small to permit of isolation.

- Lobectomy for Carcinoma of the Lung C. Eggers New York —p 211

Bronchogenic Carcinoma—Tuttle and Womack state that most, if not all, primary carcinomas of the lung are bronchogenic. At present a more detailed genetic classification is not justified. They tend to extend by the blood stream or by definite lymphatic pathways. The course of the disease as well as its symptomatology depends to a large extent on the portion of the bronchial tree in which the tumor arises. Tumors of the major bronchi give symptoms earlier, extend more slowly and are more amenable to surgical treatment. Tumors of the minor bronchi and the periphery of the lung cause fewer early symptoms and are more rapidly fatal. Histologic grading according to cellular differentiation, while it may offer some information, is subject to various interpretations and inaccuracies and must be used with great care.

Classification of Primary Cancer of Lung—Rabin and Neuhof analyzed 250 cases of primary cancer of the lung, in which 100 necropsies were done, with the object of classification for clinical purposes. Only the gross topographic features of cancer of the lung proved to be of aid in classification as to probable operability or probable nonoperability. The authors identify and describe two main groups, termed the circumscribed and the noncircumscribed types. The circumscribed type comprises a fourth of the cases. Cancers of the circumscribed type occupy the parenchymal and peripheral zones and are termed parenchymal and peripheral tumors. Regional lymph node involvement occurs later and is limited. The peripheral tumors grow from branch bronchi and may therefore be termed branch bronchus circumscribed tumors. The noncircumscribed type, to which three fourths of pulmonary cancers belong, comprises tumors growing from the main and the branch bronchi. These neoplasms are termed main bronchus and branch bronchus tumors. They present the usual invasive characteristics of cancer in the great majority of cases. Clinical, roentgenographic and bronchoscopic features serve to differentiate the circumscribed from the noncircumscribed types, on the basis of which the diagnosis as to type can be made accurately. Peripheral (branch bronchus localized type) and parenchymal tumors tend to fall into the class of operability. The great majority of main bronchus and branch bronchus tumors (with the exception of the peripheral type) do not fall into the operable class, in the sense of surgical eradication, at the time at which patients suffering from these lesions ordinarily come under observation. The indications for operation, based on the topographic classification, are outlined and five operative cases are described as illustrations of the selection of cases for operative treatment on the basis of topographic features.

Bronchial Carcinoma—During the last four and one-half years Jackson and Konzelmann have seen thirty-two cases of bronchopulmonary cancer in which bronchoscopic biopsy was confirmative. In all but three cases the endobronchial lesion was thought to be primary. The cardinal indication for diagnostic bronchoscopy is clinical or roentgenologic evidence of bronchial obstruction (a wheeze or an area of obstructive atelectasis or obstructive emphysema), and in no connection is it more valuable than in the early diagnosis of bronchial carcinoma. In addition to affording means of diagnosis, bronchoscopy will give the surgeon definite evidence regarding the level at which the lobe or lobes must be amputated to reach the upper limits of the tumor (Churchill). After roentgenographic localization of the lesion in both planes, the bronchoscope is passed down to the suspected area and the bronchial orifices are inspected. If fungating tissue is found in any of them removal of an ample amount is easy. If there is no definite involvement of the bronchial wall, but only a compression or bulge, biopsy should be postponed. It is necessary

to inspect the lesion carefully and to make certain to get tissue representative of the tumor itself and not just the peripheral "inflammatory zone." In many cases granulations are produced in the vicinity of the lesion and, of course, tissue removed from these will not show the growth. Bronchogenic tumors must be graded with caution. In the study of biopsy material from bronchogenic tumors, the fragment is by necessity small and often represents only a small part of the tumor. It has been the authors' experience that several specimens taken at various intervals have shown different degrees of malignancy, as this is determined by cytologic structure. It has been their practice to correlate the information obtained by bronchoscopy, roentgenography and microscopic study of biopsy material. The sum of these three indicates the course to be pursued. Biopsy distinguishes inflammation and benign and malignant growths. Roentgenography and bronchoscopy guide the treatment.

Salivary Calculi—Beck states that the chief difficulties in the removal of a salivary calculus may be overcome if the parts can be immobilized at will while the work proceeds. This immobilization is accomplished by means of silk traction sutures temporarily placed for the duration of the operation. The tissue is grasped close to and beneath the papilla with small forceps, and one suture is placed on each side of the wall of the duct through its orifice and given to an assistant, who exerts countertraction, converting the small orifice into a fairly large slit. At the same time this traction brings about immobilization of that submaxillary gland duct and lifts the duct away from the floor of the mouth. The sutures may be held by an assistant or may be conveniently hooked round the teeth, at the point of emergence from the mouth. With the duct orifice thus held in position a Bowman lacrimal probe is passed for detection of the calculus, after which a Bowman canaliculus knife is inserted and the duct slit open far enough to expose the calculus. At a depth adjacent to the calculus it may be necessary to complete the slitting with scissors. When thus exposed removal of the stone is not difficult.

Intensified Method of Oral Cholecystography—Stewart and Illick have devised the following technic for what they term the "intensified method of oral cholecystography" On the afternoon preceding the Graham test the patient is given two or three cups of weak tea with as much sugar as possible, accompanied by one sweet cake The dye (35 Gm) is given directly after the evening meal No breakfast is given the following morning Study of the gallbladder is undertaken sixteen hours after the administration of the dye, to estimate the mucosal function of concentration The twelve-hour examination is omitted Selected foods are then allowed that will not empty the gallbladder, extra sugar being one of the important items Additional dye is given in small doses during the afternoon and evening, along with more sugar An examination of the gallbladder for maximal concentration and intensity of the shadow is then made before breakfast the following morning, forty hours after the first dose of the dye Then a fatty meal is taken and an hour later a study is made of the function of contractability as the viscous empties Tumors and stones often come to light as the gallbladder empties Sometimes the patient has to be kept under observation for a number of hours as emptying progresses There is far more uniformity to the normal intense shadow obtained at the forty-hour observation, whereas many normal cases varied considerably in the shadow density at the sixteen-hour examination with the old technic The intensified method either does or does not give a shadow, and the faint shadow is more rare than with the former technic Fluoroscopy of the gallbladder is practical in any case in which a shadow of the gallbladder is obtained There are certain roentgen improvements which aid in obtaining these better roentgenograms A fast Bucky diaphragm is now used which permits exposures up to one twentieth of a second With such a fast technic, fuzziness of the shadow of the gallbladder due to motion is lessened The contrast obtainable is extreme and the visualization of small calculi is rendered more exact Compression is an advantage when the patient will permit it The authors employ a standard technic of 100 milliamperes and one-half second time, with less time in certain cases A fine focus tube may be used at this milliamperage The results obtained from a Graham test satisfactorily performed are as follows (1) The gallbladder is visualized, (2) the gallbladder is faintly visualized, (3) the gallbladder fails to empty properly, (4) there is no distinguishable shadow of the gallbladder and (5) gallstones are present With any of these observations, one may make certain mistakes of interpretation, the problems of which are discussed

Encephalography in Alzheimer's Disease—Menninger reports a case presenting the typical history, physical signs and mental picture of Alzheimer's disease, in which encephalography was used to exclude the remote possibilities of a brain tumor

and to support conclusively the diagnosis of Alzheimer's disease. Encephalography indicates the explanation of the symptoms and supports the repeatedly reported observations of the pathologic condition, namely, the marked brain atrophy, in this instance more pronounced on the one side than on the other

Study of Back Scatter for Roentgen Rays—Qumby and her associates point out that the amount of scatter depends on the quality of the radiation, the nature of the material on which it impinges, the volume of the material and the area of the beam The relative amount of scattered radiation is different in different directions, being greatest in the forward and least in the backward direction The portion scattered backward is of particular interest, because of its contribution to the dose delivered at the surface of the body This dose consists in part of radiation from the primary beam and in part of that scattered back by the underlying tissues Since all depth doses are determined in relation to the surface dose, it is necessary to know this accurately Moreover it is not possible to determine the erythema dose in terms of physical units (roentgens) until the intensity of a beam as measured in air can be related to that on the surface of the body Most of the disagreements in measuring back scatter may be explained by variations in the experimental conditions This is particularly true in the case of physical measurements in which instance the nature and material of the ionization chamber are extremely important When approximately the same experimental conditions are used, there is fair agreement in the results obtained. The method of choice so far has been the use of the small ionization chamber of organic materials, the assumption being that its walls have no effect on the results Some of these chambers, when calibrated against a standard open air chamber, agree with it over a wide range of quality of radiation However, the scattered radiation contains components of very long wavelength, which may be more or less completely absorbed in the walls of the chamber At the same time, the secondary radiation from these walls and from the inner electrode may introduce a disturbing factor The authors studied the problems of back scatter in radiation by measuring it with a new type of ionization chamber They found that values of percentage scatter obtained in this way are considerably higher than those obtained with so-called air wall ionization chambers The scatter increases with the irradiated area and with the effective wavelength of the radiation, the two effects being independent of each other Tables are given for the total radiation, including back scatter for a range of fields and qualities, for the variation in total radiation with field for any quality, and for the variation with quality for any field

Self-Healing Primary Squamous Carcinoma of Skin—

Dunn and Smith recently described a case of multiple primary skin cancer in a young man, with spontaneous healing of many of the lesions, and no sign of metastasis in a period of seven and a half years. In sections in the early stages, a highly malignant-looking condition was observed and, as the lesion grew older, differentiation of the cells became greater, the epithelial pearls became more completely cornified, and ultimately healing took place, with replacement of the corium by scar tissue, in which here and there degenerate remnants of epithelial pearls might be detected. The normal pattern of the corium was lost and the elastic tissue largely destroyed. In a similar case the authors cannot say what the course would have been had the lesion not been excised, but in from three to five weeks it had reached a size which squamous epithelioma usually takes as many months to attain. Rapidity of growth is usually associated with early involvement of the regional glands, but this was not so in this case. The authors think that they may be dealing with something which is not quite cancer in the ordinarily accepted sense but which cannot in its early stages be differentiated from cancer, either histologically or clinically. It is not impossible that some of the cases of primary epithelioma that are diagnosed clinically, excised, proved histologically and cured permanently are examples of the condition which they describe, and that, if they had been left to develop naturally, they would have gone through the series of changes ending in spontaneous cure. Against this view is the fact that the lesions in their two cases reached a considerable size, and experience teaches that epitheliomas that have been allowed to reach a diameter of 3 cm do badly, even with extensive surgical procedures.

and his associates carried out complete removal of the kidneys in eight male albino rats. The animals were injected with 40 units of parathyroid hormone twice daily for two days and killed forty-eight hours after the operation. The lower ends of the femurs were decalcified with nitric acid, stained with hematoxylin and eosin and examined histologically. All showed marked signs of osteoclastic bone resorption. From this the authors conclude that the action of the parathyroid hormone on the bones is independent of any direct influence it may have on the renal threshold for phosphates. Since the histologic

changes in the bones in hypervitaminosis D are entirely different from those observed in experimental hyperparathyroidism, it is difficult to believe that viosterol acts merely by stimulating production of the parathyroid hormone.

Properties of Vi Antigen of Bacillus Typhosus—Felix and his associates present observations on some of the properties of the Vi antigen (an antigen of special virulence in strains of Bacillus typhosus). The Vi antigen of Bacillus typhosus can be demonstrated by the inagglutinability of the living organisms by pure O serum or by agglutination with pure Vi serum. The two methods give equally reliable results. The development of Vi antigen is suppressed by growing virulent strains of Bacillus typhosus at temperatures between 20 and 25 C and also between 40 and 44.5 C. The application of this technic to similar studies in other bacterial species is suggested. The heat resistance of the Vi antigen is described as it is reflected by agglutination and absorption tests and by antibody formation in the rabbit. Sodium chloride extracts of cultures of virulent strains of Bacillus typhosus contain Vi antigen precipitable by pure Vi antiserum. The use of formalized extracts is suggested for the preparation of relatively potent Vi antiserum.

Primary Glaucoma.—Burnham divides primary glaucoma into two kinds: the form associated with noncupping of the optic disk and that which has cupping of the optic disk. He believes that the noncupping variety of glaucoma is due to a certain type of cyclitis without the exudation of ordinary cyclitis but with the property of causing plus tension, and that the variety of glaucoma associated with cupping of the optic disk is not due to a cyclitis, to begin with, but rather owes its origin to an inflammation of the optic disk and of the nerve immediately behind it. His conclusions are that in the beginning nearly all cases of the noncupping and cupping varieties of glaucoma can, with few exceptions, be cured by the use of scopolamine, mercury and iodide and bromide of sodium. If, however, the improvement is not satisfactory, the combined treatment may be used, that is, operation combined with the foregoing treatment. The author relies more on the medicinal treatment than the treatment by operation. In the cupping variety, he believes that in the beginning the medicinal treatment or the combined treatment is superior to the operative. In the noncupping variety, if only one eye is diseased and the other apparently not, the treatment will prevent the onset of glaucoma in the good eye. He states that his results show how wide and beneficial is the action of the nonoperative system, as advocated by him. His feeling is that the operative treatment is just about useless, being used as a last and the only resort with little belief in its ability to influence the disease.

Roentgen Treatment of Tumors—Phillips presents twenty unselected cases of bone sarcoma showing the immediate results of modern high voltage roentgen therapy. Improvement in the general condition of the patient, together with reduction in size of the tumor and relief of local symptoms, occurred in eight cases. Biopsy of the sarcoma to establish its pathologic nature is essential, either before the commencement of roentgen therapy or within the first few days of such treatment. Roentgen therapy of operable osteogenic

sarcoma is not yet justified but may improve the surgical results when applied after operation to the stump and to the thorax. For certain round cell sarcomas, especially the rare plasmacytoma, roentgen therapy is probably the treatment of choice, while temporary alleviation is not infrequently obtained in inoperable sarcomas of all types.

Operative Treatment of Facial Palsy—Ducl urges immediate investigation of the site of accidental injury in cases of facial palsy. In many instances the removal of a spicule of bone the lifting of a fractured plate of bone the decompression and cleansing of 10 mm or more of nerve with a slitting of the sheath to relieve inflammatory pressure, will ensure an almost perfect recovery, when neglect would be followed by only partial recovery with grotesque disfiguration for life. When such an investigation reveals the fact that there is an actual section of the nerve or extensive damage, a preliminary incision of the femoral cutaneous nerve may be done immediately and, two or three weeks later, a graft may be transplanted from this to replace the gap. In such a case for from forty-eight to seventy-two hours after the initial injury, one will have the advantage of being able to pick up the distal segment and verify it by faradic stimulation and will know something of the problem to be faced in making the transplant later on. No matter what the length of graft necessary in such cases, recovery is assured if the graft is transplanted successfully. Operation in cases of long standing is indicated whenever there is galvanic response in the muscles sufficient to show that the muscles have not undergone too much fibrous atrophy. The nerve can always be repaired. If there is sufficient muscle fiber left the case will be greatly improved. The quality of the result will always depend on the condition of the muscle the time element enters largely into this. The author has incised the sheath of the nerves of several cases of Bell's palsy in which the recovery was incomplete and had remained unchanged for many years. In every instance despite this long period of inactivity, the relief of the pressure by incising the sheath of the nerve has resulted in a marked improvement. He presents four recent cases.

Uveoparotid Tuberculosis—Tanner and McCurry present three cases of uveoparotid tuberculosis. In the first uveitis and unilateral parotitis were accompanied by facial paresis optic neuritis, dysphagia and palatal paresis. Mediastinal adenitis probably tuberculous in nature, was demonstrated. In the second case uveitis and bilateral parotitis and left sided facial paresis occurred. A biopsy of the parotid gland gave definite evidence of tuberculosis and there was also evidence of the same infection in the lungs. The third case showed extensive uveitis in both eyes leading to blindness in one,

unilateral parotitis and facial paresis there was a family history of tuberculosis and roentgen evidence of chronic pleurisy. The authors state that when death occurs it is due to miliary tuberculosis. This statement is based on the only three necropsies reported. An interesting feature of two of these, Souter's and Garland and Thomson's, was the presence of tuberculosis of the cardiac musculature. The authors were unable to demonstrate by clinical or electrocardiographic investigation any such involvement in their cases.

Method of Dealing with Aftercoming Head—Burns deprecates any assistance being given to the descent of the presenting part by abdominal or fundal pressure in the treatment of the normal breech. Such interference may encourage early separation of the placenta. In the fully flexed breech the arms and shoulders soon follow the birth of the umbilicus, and it is at this stage that the head is entering the pelvis. The child's body is allowed to hang from the vulva. This brings about flexion of the head and brings the nape of the neck well into the subpubic angle. The suboccipital area of the child's skull is in contact with either (1) the back of the symphysis pubis or (2) the ischiopubic ramus. The child's body weight forces the head to rotate on its horizontal axis. This method of producing flexion acts whether the head is just above the brim or whether it has already entered the pelvic cavity. When the head is already in the pelvic cavity, flexion is still necessary in order that the shortest diameters of the head will stretch the perineum and distend the vulva. In this way lacerations may be avoided and the head does not suffer undue stress. In the delivery of the head the operator should stand sideways to the buttocks of the patient and use that hand which is farther away from the mother. Only one hand should be used in lifting the child up over the mother's abdomen. The ankles must be seized when in their most dependent position, and tension applied to the legs by traction. This tension must be sufficient to keep the neck taut and should be maintained throughout the lifting. The fetal head is forced to rotate about the point of contact between the suboccipital area and the ischiopubic ramus. The perineum and vulva are distended in turn by the suboccipitomentomeal and the suboccipitofrontal diameters and finally by the suboccipitobregmatic circumference. If the weight of the child's body is not sufficient to bring the head into the pelvis, suprapubic pressure may be applied. This must be performed by the operator himself. The infant's feet are seized and tension is applied by the right hand, while with the left hand, placed directly above the pubes, pressure is applied in the axis of the brim so as to force the head through the inlet and to pass the hollow of the sacrum. This combined method of applying tension to the legs and suprapubic pressure to the head will successfully deliver the infant in almost all cases. In cases of breech delivery, separation of the placenta is not wholly a third stage phenomenon as it is in cases in which the head is delivered first. At the time when the head is

entering or has entered the pelvic cavity, so much contraction and retraction of the empty upper segments are possible that the placenta, if not actually separated from the uterine wall and retained only by the membranes, has at least ceased to function physiologically

Delivery of Breech with Extended Legs—Marshall submits a technic for breech delivery with extended legs which considers the left sacro-anterior position. The delivery is begun when the anterior buttock is visible through the vulva and the posterior buttock is impinging on the perineum. The buttocks of the mother are brought to the end of the table and the legs are placed in the lithotomy position. The bladder is emptied by catheter. With the finest hypodermic needle the region of the posterior edge of the vulva is infiltrated intradermally and subcutaneously with a few cubic centimeters of a 0.5 per cent solution of procaine hydrochloride. A 3-inch needle is inserted through this area and a fanlike superficial and deep infiltration of the whole perineum and lower part of the posterior vaginal wall is carried out. Care should be taken to ensure that the skin in the area of the proposed episiotomy is rendered completely anesthetic. Gentle ironing of the pelvic floor is proceeded with. The index finger of the right hand is now passed up behind the symphysis into the anterior groin. Steady groin traction is then made throughout the whole duration of the succeeding pains. From five to ten pains, reinforced by the groin traction, are required to bring the anterior buttock completely beneath the pubes and the posterior one firmly against the bulging perineum. At this moment a medio-lateral episiotomy is made on the same side as that on which the sacrum is descending. The traction is continued and usually with the next pain the buttocks are born. Chloroform is administered immediately on an open mask. With continued traction, or the momentum gathered with the last pain, birth as far as the umbilicus or the popliteal spaces takes place. Pressure in the popliteal spaces, directed away from the midline, flexes the legs on the thighs and detaches the feet from the vulva. A loop of cord is drawn down. The buttocks are grasped with the thumbs over the sacrum, and gentle tension is maintained. No set rule is followed with regard to the moment when the arms should be brought down. If the scapulae or the axillae readily appear at the vulva, the arms are probably flexed and thus delivery is accomplished with ease. The posterior arm is sought as soon as a definite resistance to further traction is experienced. The ankles are grasped with the left hand, the trunk is raised so that the infant's abdomen approaches the mother's right groin, while the right hand is passed up over the right shoulder and the bend of the elbow reached with the tips of the fingers. The arm is flexed and brought down over the chest and through the vulva. A little further traction, at the same time depressing the body, will frequently bring the anterior scapula into view, and the bend of the arm can usually be reached with two fingers. The elbow is flexed and the arm swept out. As soon as the arms are delivered, the body is released gently and allowed to hang from the vulva. In about half of the cases the amount of visible neck will lengthen and in a few cases the trunk may be seen to undergo a short sharp drop, the head having entered the pelvic cavity. The ankles are grasped again in a towel and the delivery of the head effected by adopting the stance and the leg traction method described by Burns.

Changes in Ovaries Resulting from Autoreaction of Zondek-Aschheim—From their clinical observations, as well as from experiments, Rosenblatt and Nathan state that in ovaries of women and rabbits during pregnancy the same changes appear that may be found in immature mice or rabbits after the injection of urine of pregnant women. These changes are less marked than after numerous injections of hormones of the anterior pituitary body, because during pregnancy the action of the hormone is not so intense. The occurrence of the Zondek-Aschheim reaction in ovaries of pregnant rabbits does not agree with Zondek's statement that an overproduction of hormones of the anterior pituitary body is to be noticed only in primates during pregnancy. To discover whether the changes that they observed in the ovaries are of a temporary character the authors isolated the rabbits after delivery

and from four to eight weeks later they took out the second ovary. The changes were no longer visible. The ovary was small, there were no hemorrhagic spots, the surface of the ovary was smooth without any corpora lutea atretica and there were numerous normal graafian follicles, proving to them that the changes were the result only of pregnancy.

Histidine Treatment of Peptic Ulcer—Bulmer treated fifty-two unselected cases of peptic ulcer with histidine. So far as possible histidine has been the sole treatment and, except in three cases, the treatment has been ambulatory. Treatment consisted of the daily intramuscular injection for three weeks of 5 cc of a 4 per cent solution of histidine. Local and general reactions were not encountered and in two cases 20 cc. was given daily for three weeks without demonstrable ill effects. The immediate results of histidine treatment, if expressed in percentages, are (1) 58 per cent of symptomatic cures with disappearance of the abnormal roentgen observations, (2) 19 per cent of symptomatic cures with persistence of some roentgen abnormality and (3) 23 per cent of failures. In a follow up, three patients relapsed and one of the apparent failures improved—the cases of gastric ulceration seemed more amenable than those of duodenal ulcer, and those with a shorter history tended to react more favorably than those with a longer history. The results with histidine seem to be better than those of the more orthodox methods and quicker of achievement, while treatment on ambulatory lines has much to commend it.

*Action of Coconcentrated Splenic Extract in Certain Dermatoses and in Asthma Pasteur Vallery-Radot and P. Blamoutier—p 457
Contribution to Study of Blood Sedimentation Methods of Blood Sedimentation A I Raponsky—p 461

Action of Splenic Extract in Dermatoses and Asthma—Pasteur Vallery-Radot and Blamoutier discuss splenotherapy in certain disorders. The splenic extracts which they used at first were painful because of insufficient removal of albumins. The aqueous extracts later employed were practically painless and as a rule produced no generalized reactions. The principal indication for splenic therapy is oozing eczema in the acute state. The effect of the extract is often rapid and may be lasting and final. The pruritus accompanying the eczema may decrease markedly even though the eczema is not definitely modified. The authors have, however, never seen appreciable improvement in the chronic dry eczemas. The results in urticaria are less satisfactory and apparently it is only the urticarias of digestive origin that may be modified by this treatment. In Quincke's edema, splenic extract has no action. Frequently the extract exerts a favorable action on the general condition, such as increased weight and improved appetite. In forty nine cases of eczema treated by them, twenty-one cures were obtained. In twelve others, marked improvement also occurred. Of thirty-five cases of urticaria there were eight cures and seven notably improved. In three cases of Quincke's edema, complete failure occurred. Seventeen cases of various types of asthma were treated, but only four were materially modified. The authors thus believe that in cases of selected type the results may be favorable.

Scapulohumeral Algebras and Their Treatment—Chaumet observed forty cases of persistent shoulder pain with certain limitations of movement. Ordinary periartthritis accounts for some. It is characterized by spontaneous pains in the shoulder more or less active at rest, acute suffering on some motions of the arm and two zones of tenderness to pressure: one externally under the point of the acromion, the other anterior to the head of the humerus and descending along the tendon of the biceps. Finally atrophy of the deltoid accompanies periartthritis when it has been of long duration. In the presence of this clinical picture, roentgenoscopy is necessary. This may be entirely negative, may show a normal shoulder but a lesion or anomaly of the cervical column or may show some particular pathologic change of the shoulder itself. The author lists five conditions of the shoulder that may be found: (1) diffuse decalcification of the articular segments or the humerus alone, (2) direct evidence of an old traumatism, as, for example, fracture of the large tuberosity with or without decalcification, (3) presence of osteophytes, (4) rugosities of the periosteum extending along a face of the surgical neck of the femur and (5) calcification of the subacromial bursa. The best treatment, he believes, is by roentgen therapy. Infra-red radiation and diathermy are also of benefit in some instances.

Pigmentary and Osseous Form of Neurofibromatosis—Grenet and his co-workers describe several cases of skin pigmentation often associated with various types of bony disorders which are closely allied to Recklinghausen's disease. They were able to collect fifteen cases in about a year. This form or its skeletal changes, is relatively frequent. A pure osseous form probably exists but is much more difficult to identify. They have almost come to the conclusion that in the majority of the cases the pigmentary and osseous complex is

more a stage of evolution of neurofibromatosis than a definite larval form. The practical conclusion is that Recklinghausen's disease, especially such larval forms, must be recalled as a common factor in osseous disorders. When suggestive bony abnormalities exist, one must search carefully for Recklinghausen's disease in the family tree.

*Congo Red Test in Different Forms of Hepatic Diseases R del Zoppo—p 89

Clinical Roentgenologic Contribution to Study of Congenital Osseous and Articular Syphilis G Liuzzo—p 95

Contribution to Technic of Blood Transfusion New Apparatus P Bost—p 99

Congo Red Test in Hepatic Diseases—Del Zoppo used the following technic in testing twenty-eight patients presenting various diseases of the liver. Five cubic centimeters of the patient's blood is taken from one arm and is placed in a tube containing 1 cc of a 5 per cent solution of sodium citrate. This is followed by immediate injection in the arm of 1 per cent congo red in physiologic solution of sodium chloride. After four and sixty minutes respectively from the time of injection, 5 cc. of blood is removed from the other arm and each specimen is placed in a separate tube containing 1 cc. of the same solution of sodium citrate. The tubes are placed on ice for several hours and afterward are centrifugated. The normal plasma is decanted with a standard 1:10,000 solution of congo red (1 cc. of normal plasma plus 1 cc. of congo red solution plus 9 cc of distilled water). The decanted plasma is compared with the remaining two diluted plasmas (1 cc. of plasma and 10 cc of distilled water) by means of the colorimetric method and artificial light. The amount of color retained in the plasma is next determined. The hepatic function of all patients was studied by means of the glycemic and the amino acid curves. The author found the test an important aid to the study of hepatic function. It is applicable to diseases of the kidney presenting reticulohistiocytic lesions. Congo red in general ranks equally with other chromodiagnostic tests in the study of the reticulo-endothelial system. In hepatic diseases with acute and chronic intense biliary stasis, the amount of color in the plasma was high. The color rate was average in diseases with mixed lesions, such as various forms of cirrhosis, hepatic syphilis, neoplasms and abscesses of the liver all having combined parenchymal and reticulo-endothelial lesions. In diseases with a parenchymal disturbance and a retention of the biliary pigment in the blood, the rate of color was markedly high. This must be attributed to a saturation of the reticulo-endothelial elements on the part of the biliary pigment.

Clinical Considerations on Treatment of Syphilis During Pregnancy R Sassi—p 470

*New Sign Indicating Expulsion of Fetus After Intra Uterine Death Causes of Determination of Labor by the Fortieth Week P Talamo—p 483

Expulsion of Fetus After Intra-Uterine Death—Talamo states that the appearance of painful intense turgor of the breast associated with profuse milk secretion during the last half of pregnancy is an unmistakable sign indicating imminent expulsion of the fetus after intra-uterine death. The author discusses the mechanism of production of the sign in its relation to that of the production of uterine contractions by which the onset of labor is determined. According to the hypothesis of the author there is during pregnancy an equilibrium between estrogenic substance and the antithetical hormones (lutem and luteinizing factor of anterior pituitary-like principle during the first half of pregnancy and other undetermined hormones during the last half). The rupture of this equilibrium, either normal or pathologic, results in the production of the uterine contractions which determine the onset of labor. Normally the hormonal equilibrium is disturbed by the fortieth week because of the accumulation of estrogenic substance in the blood. When the fetus dies in the uterus before term, the quantity of estrogenic substance is not enough to disturb the hormonal equilibrium, which later breaks down by the decrease of the antithetical hormones in the blood, since their production stops as soon as the fetus dies. The hormone unbalance is reached

during the time elapsed between the death and the expulsion of the fetus. When for some unknown reason, probably related to the death of the fetus, the hypophysis develops a hyperactive function during this period, a large quantity of hypophyseal hormones is thrown into the blood and their action prevails over that of estrogenic substance. In these cases the sign described by the author appears. The intense lacteal and mammary symptoms, caused by the action of the prehypophyseal hormones, are the first to appear and their appearance indicates a more or less immediate expulsion of the fetus by the oxytocic action of the posthypophyseal hormones. In the author's two cases a dead fetus was expelled within twenty-four hours of the appearance of the sign.

Surgical and Climatic Therapy of Coalgia O A Marottoh—p 2380

Reactivation of Malaria by Calcium Chloride—Videla attempted to produce the reactivation of latent malaria by the administration of either berberine sulphate, by the oral or intramuscular routes, or epinephrine chloride, by the intramuscular route, and obtained 100 per cent negative results in eighteen cases. Daily intravenous injections of 10 cc. of a 10 per cent solution of calcium chloride gave 66.5 per cent positive results in six cases. The reactivation of latent malaria by calcium chloride is produced as early as the first, second or third injection and coincides with a positive Henry ferroflocculation test (+ or ++), and with the existence of splenomegaly of the first or second degree. Monteleone, who originated the method of administration of calcium chloride injections used by the author, explained the action of calcium chloride as caused by a vasomotor reaction by which the malarial parasites appear in the blood.

Restitution of Endocrine Functions After Gynecologic Surgery—Cirio and Murray say that either ovarian or endometrial grafts, implanted after hysterectomy and ovariectomy, undergo a rapid process of degeneration with early reabsorption of the graft. Ovarian and endometrial grafts, simultaneously implanted immediately after hysterectomy and ovariectomy in distant structures (the omentum and a superficial vein in the forearm, respectively, in the experiments of the authors), "take" and show life and normal histologic characteristics six months after their implantation. Ovarian and endometrial grafts, simultaneously implanted immediately after hysterectomy and ovariectomy in the same structure and in contact with each other, undergo manifest lytic changes. The results of these experiments verify the previously reported concept of the existence of a synergic activity between the ovary and the uterus. The authors found that the great omentum is the seat of selection for the implantation of ovarian grafts, which show life and normal functions one year after their implantation. The endothelial surface of the internal vena saphena is the seat of selection for the implantation of the graft when, because of its aseptic conditions if ovarian or its nature if endometrial, it cannot be left in the great omentum. Ovarian and endometrial autografts and homografts, implanted immediately after oophorectomy and hysterectomy, respectively, give satisfactory results in preventing the symptoms of endocrine insufficiency, which regularly follow those operations. The symptoms of endocrine insufficiency do not appear or, if they do, they are greatly attenuated by timely grafting, both when menstruation continues regularly and when it does not. As a rule, grafts performed late after mutilating operations do not give satisfactory results. The graft took and gave satisfactory results in only one patient out

of five in whom ovarian homografts were implanted eighteen days after oophorectomy. Menstruation in the patient was regular after grafting and she had an increased basal metabolism (44.3 per cent). The authors state that one should resort to ovarian and endometrial autografts and homografts immediately after mutilating operations of the reproductive organs in women in order to reestablish the endocrine functions.

Development of Human Vagina from Formation of Distal Portion of Müller's Vagina to Beginning Replacement of Müller's Epithelium by Sinus Epithelium R Meyer—p 639

Intermediate Metabolism During Pregnancy—Bokelmann and Bock point out that in former studies on fat metabolism they observed that pregnant women respond to a fat tolerance test with a considerable increase in the acetone bodies of the blood and that the elimination of the total acetone, but particularly of the beta-oxybutyric acid, is considerably increased in the urine, while in nonpregnant women, although the elimination of acetone is increased, the beta-oxybutyric acid remains unchanged. The studies reported here were begun on the basis of the observation that the fats form acetone bodies, which, in case of abstention from carbohydrates or under the influence of oral fat tolerance tests, are eliminated in the urine in considerable quantities, especially in pregnant women. They conclude that the blood and the urine of pregnant women contain a larger amount of acetone bodies than the blood and the urine of nonpregnant women. The blood of pregnant women contains also much larger amounts of fatty acids than does that of nonpregnant women. Following the oral administration of large quantities of fat, while at the same time the diet contains relatively large amounts of carbohydrates, the blood contains more fatty acids and more acetone bodies and the urine likewise has more acetone bodies. These reactions are much greater in pregnant than in nonpregnant women.

Adrenaltropic Substance of Hypophysis—Anselmino and his associates show that the anterior lobe of the hypophysis contains a substance that produces in rats and mice histologic changes in the adrenal medulla. These changes are characterized by reduction of the chromaffin substance formation of vacuoles in the marrow cells and hyperemia of the blood spaces. They are noticeable two hours after a single injection of the active substance, and they reach their maximum from six to twelve hours after the injection; however, they are demonstrable also in the prolonged experiment. Control tests prove that the changes of the marrow cells are specific for the extract of the anterior lobe of the hypophysis. The physical characteristics of the hypophyseal substance that acts on the adrenal medulla are essentially the same as those of the other extracts of the anterior lobe of the hypophysis. In attempts to separate the adrenaltropic substance from the other hormones of the anterior lobe of the hypophysis it was found that it is not identical with the thyrotropic, the pancretotropic and the corticotropic substance, the hormones of the fat and of the carbohydrate metabolism, and the gonadotropic hormone. Its differentiation from the corticotropic hormone permits the separate modification of the adrenal cortex and medulla. The authors discuss whether the changes in the adrenal medulla were the manifestations of a stimulation of the medulla and answer this question in the affirmative. Finally they consider the blood sugar action of the substance and discuss the possible identity of the adrenaltropic substance with the blood sugar increasing substance of the anterior lobe of the hypophysis (the contra-insular hormone of Lucke and the diabetogenic substance of Houssay).

Anterior Lobe of Hypophysis in Castration Obesity—Schultze determined the histologic behavior of the anterior

lobe of the hypophysis in castrated female rats. He observed a difference in the number of basophilic cells in animals with and without castration obesity. Animals that gained a considerable amount of weight following castration had more basophilic cells than those that did not. The authors call attention to similarities with Cushing's pituitary basophilism and with the constitutional obesity of Kraus.

Palpable Metastases of Lymph Nodes in Pulmonary Tumors.—In a patient who had a tumor in the left pulmonary hilus Takino observed that the first metastasis was not in the left supraclavicular lymph nodes but in those of the right side. He points out that in case of abdominal tumors particularly cancer of the stomach, the left supraclavicular gland (so called Virchow gland) is most carefully examined for metastases. Later he observed three cases of pulmonary neoplasm in which the tumor was in the left upper lobe, in the left hilus and the metastasis was only in the right supraclavicular lymph nodes. This indicates that in case of pulmonary and mediastinal tumors not only the left but also the right supraclavicular lymph nodes should be examined. The author watched the mode of metastasization in fifteen other patients, most of whom had pulmonary tumors and a few of whom had mediastinal tumors. He found that, if the tumor is located in the upper lobe and spreads toward the surface and the apex of the lung the first metastases develop in the homolateral supraclavicular lymph nodes. If the tumor is near the hilus, the metastasis is at first on the contralateral side. If the tumor is in the pleura, metastasization takes place in the homolateral axillary lymph nodes. In case of metastasis in the homolateral supraclavicular lymph nodes the tumor must be in the upper lobe somewhat removed from the mediastinum and not near the main lymph vessels. In case of metastasization in the supraclavicular lymph nodes of the opposite side, the growing tumor exerts pressure on the chief lymph channels and the cancer cells are carried through anastomoses to the opposite side. Not all metastases can be explained on the basis of the anatomic conditions of the system of lymph vessels, for the retrograde transport or the "paradoxical lymph stream" may play a part. If the cancer cells are carried to the homolateral supraclavicular lymph nodes even if pressure was exerted in the beginning on the main lymphatic channels, it must be assumed that either not all channels were compressed or new lymph channels had been formed. In most cases metastasization takes place early, within two months after the appearance of the first symptoms. They help to localize the tumor.

Prevention of Postoperative Wound Complications in Thoracocautery.—Sattler discusses two typical complications of endothoracic pleuroscopy and pleurolysis, namely, postoperative emphysema and suppuration of the thorax wound. Both complications are hardly ever of vital significance, but they annoy the patient, impair the immediate result of the intervention and eventually may impair the final results. To prevent emphysema, careful management of the operative wound is important. If a large instrument has been used, it is not sufficient merely to close the cutaneous wound, for a comparatively large muscular wound would remain and nothing would prevent the air from entering the tissues. It is necessary to close the wound in layers. He further shows how postoperative suppurations may be caused by tissue injuries that are caused by prolonged duration of the operation, by bruising and drying of the wound. If this is the case, the wound should be freshened by excision before the suture is made, for thus healing by primary intention may be obtained. To prevent specific infection of the

wound the intervention should be omitted in case of extensive, casuous tuberculosis of the pleura.

Method of Culturing Tubercle Bacilli from Punctates.—Sargo places a small quantity of the punctate to be examined in test tubes that contain culture medium. According to the width of the test tube the amount is 0.5 or 1.5 cc., the object being to introduce such a quantity that about three fourths of the surface of the culture medium remains free. After the test tube has been closed it is inclined several times so that the punctate runs over the surface of the culture medium. In the incubator the tubes are left in the vertical position, but the process of moving the tubes is repeated from time to time (about four times each week) during the entire period of incubation that is for at least two months. However the moving should be done with great care, to give the organisms the opportunity to adhere to the surface without being flooded off again. The author employed stained egg culture mediums a red and green one for each punctate. He employed this method for the examination of various exudates and punctates from serofibrinous pleurisy, pneumothorax, tuberculous empyema, tuberculous peritonitis, tuberculous pericarditis, tuberculous meningitis, tuberculous articular exudate and the pus of tuberculous glands. Of 123 cases, 103 gave positive results. The method was proved particularly valuable in the spinal punctates from patients with tuberculous meningitis, of eighteen cases, seventeen gave positive results. The method is simple and reliable and it can be used for all clinical and diagnostic purposes.

Functional Test of Cardiopulmonary System. E. Simonson—p. 1831

Pregnancy and Physical Exertion.—Schroeder and Franz determined the working capacity of women during pregnancy and compared it with the working capacity four months after delivery. The period of recovery, that is, the time the circulation and metabolism require to return to normal after an exertion was found to be longer during pregnancy than in the absence of pregnancy. The authors think that this indicates a certain instability of circulation and metabolism in pregnant women but that this instability is not observed during the exertion. They conclude that work requiring light and medium exertion may be done up to the end of pregnancy without detrimental effects on the pregnant organism. They consider it false humanitarianism to forbid a pregnant woman to work and they maintain that work is the best preparation for the delivery and prevents worrying and anxiety.

Irrigation and Iodized Oil Treatment of Empyema.—Boller and Makrycostas review the treatment of empyema by means of irrigation and injection of iodized oil which was described by Boller in the *Wiener Archiv für innere Medizin* (23 37 [Oct. 1] 1932, abstr. THE JOURNAL, Dec. 24, 1932, p. 2229), and they describe eight more cases in which they employed this combination of irrigation and iodized oil injections. Whereas in the first report only cases that were treated with irrigation and iodized oil were described, this report includes three cases in which the irrigation and iodized oil treatments had to be followed by Bülow's drainage. The latter was well tolerated and with the aid of regular fillings with iodized oil the treatment could be successfully concluded in a comparatively short time. The authors recommend that first in every case of pleural empyema the treatment with irrigation and iodized oil be given several times, for in the majority of cases this therapeutic method will succeed. In empyema of severe septic character, however, it is not sufficient. Here, it should be followed by Bülow's drainage, which in turn should be aided by filling with iodized oil.

Action of Growth Hormone on Dwarfism in Mice—Kemp treated dwarfed mice, in which the inhibition of growth was caused by a hereditary defect of the anterior lobe of the hypophysis, with the isolated growth hormone of the anterior hypophysis. He found that this treatment induced a well proportioned growth in the various organs, including the long tubular bones, which increased considerably in length. The thymus, however, with a luxuriant growth of the parenchyma, grew much more than the other organs.

Delivery as Work Process—To determine the amount of work the organism performs during the process of delivery, Schroeder and Franz obtained specimens of respiratory air from parturient women at fifteen or thirty minute intervals. They determined the oxygen consumption of seventeen women from the onset of the labor pains until five hours after delivery. They show a curve they obtained in a healthy primipara. The peaks indicate the increased oxygen consumption during a uterine contraction and the depressions represent the consumption during the pain-free interval. During the period of dilatation the curve rises gradually, but during the rupture of the bag of waters and the subsequent pain-free interval it decreases again. The curve reaches the highest peaks during the period of expulsion, for now the work of the uterine muscle is complemented by the pressure of the abdominal muscles. After the birth of the child, the oxygen consumption decreases considerably but it does not reach the preparturient level until four hours later. The oxygen consumption that is normal for the nonpregnant organism is not attained until about eight days after delivery. In comparing the work performance of the delivery of old and young primiparas, the authors were able to corroborate the results obtained by Frey with the hysterotonograph, that the old primipara has to meet the same physiologic requirements in the course of the delivery as does the young primipara. The old primipara consumes during delivery no more oxygen than does the young primipara. The authors studied the effects of various analgesics on the work process of birth and found that the oxygen consumption per unit of time was not reduced under the influence of the analgesics.

Influence of Amyl Nitrite on Cerebrospinal Fluid Pressure—Tests on normal persons convinced Stefan that the cerebrospinal fluid pressure is much lower when the person is lying down than when he is sitting up and for this reason he advises that the pressure be tested only while the person is lying down. The inhalation of a few drops of amyl nitrite leads to a florid reddishness and a feeling of heat in the face as well as to a cerebral hyperemia. These manifestations are the result of an increased inflow of blood, which is caused by a paralysis of the vasomotor centers with consequent dilatation of the vessels. Its inhalation during lumbar puncture is accompanied by a dilatation of the intracranial vessels and by an increased production and a greater pressure of the cerebrospinal fluid. He studied the pressure changes in 151 persons, of whom sixty-two were normal, twenty-two had space limiting processes, thirty-two had cerebral arteriosclerosis and thirty-five had postencephalitic parkinsonism and other chronic inflammatory cerebral disturbances. He found that the normal persons and those with space-limiting cerebral processes reacted with an enormous increase in the cerebrospinal fluid pressure to the inhalation of amyl nitrite, while patients with cerebral arteriosclerosis or with chronic inflammatory disturbances of the brain showed almost the opposite reaction. He thinks that these tremendous differences in the action of the amyl nitrite are due to the fact that its effect is limited in vascular and in chronic inflammatory disturbances of the brain in that the extent of the vascular dilatation is lesser, that the number of vessels which become dilated is smaller, or that both factors are involved. In a number of patients in whom the diagnosis had not been decided

as yet, it was possible to determine it by means of the amyl nitrite action. The subsequent necropsics corroborated the diagnostic value of the method. These observations indicate that the amyl nitrite test is helpful in the differentiation between the space-limiting processes and the chronic inflammatory or vascular disorders of the brain. However, it is not suited for the differentiation between diseased and normal brains.

Tubercle Bacillema in Course of Acute Polyarthrits—Reitter and Lowenstein review their former studies on tubercle bacillema in polyarthrits, pointing out that in 1928 Reitter first advanced the theory that tuberculosis plays a part in acute polyarthrits. During 1930 and 1931 they examined cases of acute polyarthrits for tubercle bacillema and concluded that acute polyarthrits is an exudative-inflammatory phase in the course of a tuberculous reinfection. At that time they stressed that tubercle bacillema alone is not sufficient to produce the symptomatology of acute polyarthrits but that the tubercle bacilli must enter a connective tissue that is highly susceptible to tuberculosis, an allergic or hyperergic tissue. Reitter emphasized in 1928 that in rare instances tubercle bacilli are found in the articular fluid and that at certain times patients with polyarthrits are highly susceptible to tuberculin. The authors deplore that, although they always stressed the clinical manifestations and showed that tubercle bacillema may be present at the same time, many clinicians, pathologic anatomists and bacteriologists gave their attention only to the bacillema and took an attitude as if the foundations of the pathologic anatomy of tuberculosis had been attacked. With this attitude many began the search for tubercle bacilli and were gratified when they obtained negative results, in many cases examining only one specimen of blood from each patient. Nevertheless, a few investigators corroborated the authors' observations.

Aid in Palpation of Arterial Pulse—Wilder calls attention to the fact that it is difficult to detect by palpation the pulse of the dorsalis pedis artery, for even experienced examiners are sometimes unable to agree on their observations. He thinks that this difficulty may be remedied by an old but almost forgotten method, namely, by applying oil to the skin. By putting oil on the dorsum of the foot, the palpation of the pulse becomes much easier. Pulsations that were hardly palpable before become much clearer, and those ordinarily not perceptible now become palpable. In palpating muscles in order to determine areas of hardness, nodules and other pathologic conditions, the application of oil is likewise helpful for it is much easier to palpate the details in the underlying tissue if the finger glides over a smooth surface. Moreover, oil palpation is helpful also in palpating the liver and other abdominal organs.

Studies on Reticulocytes in Pulmonary Tuberculosis—Szour and Bergenbaum studied the behavior of the reticulocytes in 200 cases of pulmonary tuberculosis. They employed the vital staining of the blood drop according to the method of Levaditi-Ehrlich. After preliminary studies on the reticulocytes of normal persons which disclosed that in adults the number of reticulocytes varies between one and five per thousand of the erythrocytes, the authors studied the number and then the behavior of the reticulocytes in patients with pulmonary tuberculosis. They found that these studies are valuable in the diagnosis, the prognosis and the evaluation of therapeutic methods. In summarizing their observations they state that the curve of the reticulocytes in the course of pulmonary tuberculosis reflects the combat between the organism and the tuberculous infection in the region of the erythroblastic system of the bone marrow. The quantitative and qualitative changes in the reticulocytes that enter the periphery are exact indicators of the relationship between the intensity of the tuberculous infection and the defense powers of the organism.

Tryptophan Reaction in Tuberculous Meningitis —Schumacher gives a description of the technic of the tryptophan reaction in tuberculous meningitis. To from 2 to 3 cc of cerebrospinal fluid is added 15 cc. of a concentrated hydrochloric acid solution and 2 drops of a 2 per cent solution of formaldehyde (prepared fresh each time from the usual 40 per cent solution by preparing a dilution of 1:20), and this mixture is shaken. Then it is allowed to stand for four or five minutes and after that is layered with 2 cc of a 0.06 per cent solution of sodium nitrite. If the reaction is positive, there appears in the course of two or three minutes, at the site where the two fluids meet, a delicate violet ring. If there is no change of color or if a brownish shade appears, the reaction is negative. The author reports his experiences in 114 cases. In thirty-two cases of tuberculous meningitis the reaction was always positive. In none of the cases of tuberculous meningitis was a negative reaction found. The cerebrospinal fluid of eighty-two patients with nontuberculous disorders of the brain or of the meninges served as a control. Of these, eight gave a positive tryptophan reaction. Seven of the latter were false positive reactions that developed in purulent, hemorrhagic or xanthochromic cerebrospinal fluids. In one instance the tryptophan reaction was a complete failure. However, the differential diagnosis was not in doubt in this case for the presence of a cerebral tumor had been recognized. The author concludes that the tryptophan reaction permits a quick and definite differentiation of tuberculous meningitis from disorders with a similar symptomatology.

Ovulation and Conception —To test the Knaus-Ogino-Smulder theory of the period of physiologic sterility, Weinstock selected 416 women in whom pregnancy had taken place after a single coitus, the exact date of which was known as well as the dates of at least the last three menstruations and the length of the menstrual cycle. The women were healthy. He shows the length of the menstrual cycles and that there are comparatively few women in whom the menstrual cycle is always of the same length. Another table showing the day of the single fertilizing coitus within the menstrual cycle indicates that conception is possible on every day of the cycle but that there are fluctuations in the fertility and that conception is most likely between the fifth and tenth day of the cycle. The author concludes that practical experience indicates that there is no sterile period within the menstrual cycle.

Hormone Disturbances as Cause of Menstrual Disorders —The observation that pregnancy is rare in diabetic women induced Liegner to investigate whether less pronounced pancreatic disturbances influence fertility. In former investigations he had observed in guinea-pigs that the resection of the pancreas was followed by severe disturbances in the gonads and that fertility was greatly reduced. He now reports that he observed women with a deficient function of the insular

apparatus in many of whom menstruation was abnormal. He attempts to explain these menstrual disturbances on the basis of changes in the ovaries of animals the insular function of which had been interfered with. These changes indicate that menstruation may be retarded and reduced in intensity, or, the failure of the formation of a corpus luteum (the absence of the inhibitory factor) may result in atypical, acyclical and prolonged hemorrhages. The author states that he employed insulin in a number of women with menstrual disturbances, in whom various treatments, including the administration of estrus-inducing hormones had failed. In many instances the results were favorable in that the menstruation became regulated within a comparatively short time. However, precaution is necessary because in the beginning some of these patients do not tolerate insulin well. Moreover, it is generally necessary to repeat the insulin treatment after a certain interval. The first series of insulin injections is usually continued for four weeks.

*Surgical Treatment of Urinary Incontinence W. Mestitz —p 3046

Late Sequels of Eclampsia Particularly Renal Changes —Heynemann asserts that there is no definite proof that pregnancy nephrosis or eclampsia ever causes chronic glomerular nephritis. If they ever do so, he thinks that it is an extremely rare occurrence. He maintains that the damages caused by eclampsia or pregnancy nephrosis on the renal parenchyma, or the tubules as well as the glomerules, heal as a rule, at any rate they do not produce severe changes. However, eclampsia and pregnancy nephrosis do have a damaging influence on the vascular system, which becomes manifest in headaches, vertigo, increased blood pressure, changes in the vessels of the fundus oculi, cardiac changes, nephrosclerosis and apoplexy. The changes in the cerebral and renal arteries are the most important ones, but eclampsia and its preliminary stages are not the only cause of these changes, for age and hereditary predisposition likewise play a part. However, in approximately 5 to 6 per cent of the cases of eclampsia and pregnancy nephrosis severe vascular changes occur. As a rule there develops nephrosclerosis, but the more severe manifestations generally do not become evident until after the fortieth year of life. In the pathogenesis of malignant sclerosis and its transitional cases, eclampsia and its preliminary stages play a rather important part. In from 1 to 15 per cent of these disorders, the development of a malignant sclerosis or of one of its preliminary forms must be expected. If this is the case, an unfavorable outcome may be expected at an earlier age. If hypertension and albuminuria develop in women who have passed through an eclampsia or its preliminary stages, the existence of a nephrosclerosis and not of a chronic nephritis should be considered first, and, if signs of renal insufficiency appear in women under 40 years of age, malignant sclerosis or one of its preliminary stages should be thought of. The treatment should aim at counteracting the hypertension and the arteriosclerosis. The after examinations never revealed hepatic changes. The author concludes that a former eclampsia or a pregnancy nephrosis do not contraindicate a new pregnancy. A nephrosclerosis, however, particularly its malignant form, may become exacerbated by a new pregnancy.

Surgical Treatment of Urinary Incontinence —Mestitz points out that the method to counteract the urinary incontinence resulting from a damage of the vesical sphincter must try to imitate the physiologic mechanism. An effort must be made to lift and bend the urethra, particularly its posterior wall, toward the symphysis. This aim is accomplished best by means of the artificial formation of a sphincter from the vesicovaginal fascia. The method can be used in virgins and in multiparas. In most cases urinary incontinence is accompanied by sinking or prolapse of the anterior vaginal wall, and this makes the procedure even more simple. Moreover, the method can be employed in the absence of the uterus as well as in women during the reproductive age. He limits the intervention to the

suture of the connective tissue fascia and dispenses with the exposure of the vesical musculature. In this respect his procedure differs from that of several other surgeons. However, he considers it important that the transverse sutures be made in such a manner that the fascia is grasped far outward in the region of the levator muscle. If this is done, the function of the fascial clasp is effectively supported by the action of the puborectal muscle. In cases of especially severe incontinence or in case of relapse following his fascial suture, the author employs the method of Goebell-Frangenheim-Stoeckel. Goebell formed a substitute for the urethral sphincter from the pyramidal muscles or from a strip of the rectus muscle, while Frangenheim suggested the use of flaps of the anterior rectus sheath. Stoeckel introduced this method into gynecologic surgery. The formation of the sphincter from the vesicovaginal fascia or the Goebell-Frangenheim-Stoeckel method was employed by the author in eleven cases, and the results were favorable in eight. In addition to these two methods, he tried the formation of the urethral sphincter from the bulbocavernosus muscle. This method was successful in six out of eleven cases. He concludes that in uncomplicated, mild or medium severe cases the sphincter formation from the vesicovaginal fascia is the best method and that in more severe cases or in relapses the method of Goebell-Frangenheim-Stoeckel is the most satisfactory.

*Experimental Conservation of Blood Yu. M. Irger, P. E. Ginzburg, Z. S. Sosonkin, A. S. Mazeleva, P. Yu. Dobruskina and S. N. Verzhynskaya —p. 53

Histologic Structure of Thyroid in Exophthalmic Goiter—According to Veber and Elenevskaya, the thyroids of patients who have exophthalmic goiter and who have been subjected to the preoperative treatment of compound solution of iodine exhibit as a rule the histologic picture of a colloid goiter with pronounced proliferation of the epithelial layer. The authors have not encountered any so-called primary forms of hyperthyroidism in their material. They found the method of Mallory and of Kraus for staining the colloid a valuable histologic procedure in evaluating the severity of the disease. They failed to establish a definite relationship between the histologic picture and the severity of the disease in the cases of exophthalmic goiter treated preoperatively with compound solution of iodine. Preoperative administration of compound solution of iodine brings about an improvement in the clinical picture and a histologic alteration in the direction of diminution of the polymorphism of the follicles and the epithelium. The authors conclude that the essence of the morbid process is to be sought in its hormone activity rather than in the histologic picture of the gland.

Experimental Conservation of Blood—Irger and his associates drew blood from the femoral artery of a dog and collected it into a vessel containing 50 Gm. of sodium citrate, 7 Gm. of sodium chlorate, 0.04 Gm. of magnesium sulphate and 0.2 Gm. of potassium chlorate in 1,000 cc. of distilled water. The blood was added to this fluid in an equal amount. The authors found that the erythrocytes remained unchanged for about fifteen days after which period they diminished in number by 12.9 per cent, by 39.6 per cent on the thirty-fifth day and by 76 per cent on the forty-fifth day. Microscopic study showed that the erythrocytes maintained their form until the twentieth day, after which they displayed a gradual shrinkage resembling erythrocyte shadows on the thirty-eighth day. The diminution in the leukocyte count took place much earlier. On the fifth day it was diminished by 7.4 per cent, on the fifteenth day by 27.2, on the thirty-fifth day by 66.6, and on the forty-fifth day by 84.2. The leukocytic formula changes in the direction of diminution of neutrophils and a relative

increase in lymphocytes. The number of reticulocytes diminished gradually, there being none present after the forty-fifth day. The lowering of the respiratory function of the erythrocytes (determined after the method of Barcroft) took place slowly and the hemoglobin changed little. The authors have noted a gradual diminution of the glycogen content of the blood. The inorganic blood phosphorus increased up to 10 on the fifth day, 20.5 on the eighteenth and 29.3 on the forty-third day. There was noted a gradual lowering of the osmotic tension of the erythrocytes, and this corresponded to the increase in the inorganic phosphorus. Parallel with the fall in sugar content there was an increase in lactic acid. The authors insist that the strictest asepsis must be maintained in the conservation of blood, such as wearing of a mask and of gloves. Blood may be kept sterile for forty-five days at room temperature. Hemolysis was absent in conserved human blood for twenty-one days and in dog's blood for forty-five. Because of the morphologic and biologic alterations noted, the value of conserved blood for purposes of transfusion is much less than that of the fresh blood.

Focus of Infection in Pathogenesis of True Rheumatism—According to Koritskiy, clinical observations and anatomic and experimental studies indicate the existence in genuine cases of rheumatism of a sepsis with a hyperergic reaction. The author observed that rheumatic patients are chronic carriers of a focal infection located in the pharyngeal region. They are best demonstrated by rotating the tonsil. The peculiarity of such a focus is its painless chronic course characterized by suppuration in the various areas of the pharyngeal region with a selective localization in the supratonsillar, pretonsillar and retrotonsillar sinuses rather than in the tonsils themselves. The infectious process here runs a chronic latent course, with occasional acute exacerbations in the form of acute tonsillitis. Inspection of the tonsils and the adjacent sinuses reveals, as a rule, erosions, ulcerations, indurations, hypertrophy or scar formation. One may observe here all stages of an inflammatory process, from hyperemia and infiltration to breaking down of tissue and suppuration with consequent scar contraction. The process is a tissue reaction to a polymorphous bacterial flora, particularly of the streptococcus group, to bacterial toxins and to the products of the broken down albumins. The author regards such a focal infection not only as a port of entry of infection but also as a lesion capable of influencing the organism as a whole so as to alter its reactivity. The organism reacts to repeated exacerbations in a manner different from its original reaction. There may develop an unusual, abnormal, allergic reaction laying the foundation for rheumatic disease.

THE DIFFERENTIAL DIAGNOSIS OF THE LEUKEMIC STATES

WITH PARTICULAR REFERENCE TO THE IMMATURE
CELL TYPES

ROY R. KRACKE, M.D.
AND
HORTENSE GARVER, M.S.
EMORY UNIVERSITY, GA.

A thorough knowledge of hematopoiesis is essential for a careful differentiation of the various types of leukemia. No longer are these dyscrasias considered "diseases of the blood" but rather dysfunctions of hematopoietic tissues.¹ Until the second decade of the twentieth century with the work of Reschad and Schilling-Torgau² and others, there were recognized only two types of leukemia: myeloid, arising in the bone marrow, and lymphatic, having its origin in the lymphoid tissue. The recognition of a third type of leukemia involving the monocytic series of cells has engendered new ideas concerning the origin and classification of blood cells.³ As a result of this stimulus, many conflicting theories have arisen.

PRESENT CONCEPTION OF HEMATOPOIESIS

Investigators are in accord only in a single concept—that all blood cells have their origin from the mesenchymal cell of the mesodermal layer in the embryo.⁴ From this point, opinions diverge in many directions.

Pappenheim⁵ and later Maximow⁶ are considered the founders of the monophyletic theory. According to this view, in adult life all types of blood cells have a common origin from a single primitive stem cell with azurophilic, basophilic cytoplasm, which is called "lymphocyte" by some investigators and "hemocytoblast" (Feratta⁷) by others.

According to the polyphyletic or dualist theory, advanced by Ehrlich,⁸ this common ancestral cell is not present after birth but there are two precursors in postnatal life: the myeloblast giving rise to granulocytes, erythrocytes and monocytes and the lymphoblast, from

which mature lymphocytes develop. Naegeli,⁷ although not in complete accord in minor details, is considered a strict dualist, believing that granulocytes, red cells, platelets and monocytes arise from the myeloblast. Piney¹ has adopted a modified polyphyletic point of view. He believes in the existence of three postnatal stem cells: (1) an erythroblast, which has a unique maturation cycle and produces mature red blood cells, (2) a myeloblast, which is the precursor of both myeloid and monocytic leukocytes, and (3) a lymphoblast, which gives rise to lymphoid cells.

Further divergence is found in the triphyletic concept, championed by Schilling⁸ and sponsored by many of the more recent contributors, including Aschoff and Kiyono,⁹ Cunningham,¹⁰ Dameshek,¹¹ Sabin¹² and Merklen and Wolf.¹³ This school places the monocytic series of cells in a separate cycle of maturation, tracing its origin from a postnatal stem cell, the monoblast, which in turn arises from a primitive stem cell of the reticulo-endothelium. This primitive stem cell is found in all blood-forming tissues. In the bone marrow it gives rise to myeloblasts and megaloblasts, in lymph tissue to lymphoblasts, in outside reticulo-endothelium to monoblasts and to macrophages or fixed tissue cells. From this point of view there are three sites of hematopoiesis: the bone marrow, the lymphoid tissues and the so-called reticular-endothelial system, and as a result three respective types of leukemia.

Leukemia is defined by Musser and Wintrobe¹⁴ as "a morbid condition characterized by widespread hyperplasia of the leukopoietic tissues." Piney¹ does not consider simple hyperplasia to be sufficient description of the existing pathologic condition. He believes that in almost every case of myeloid leukemia there is a tendency toward "Lenaz's monophasic anaplasia" in which there are great aggregates or foci of cells of a single immature type, at which point maturation has stopped, generally at the leukoblast stage. Surrounding these foci there is a simple hyperplasia.

At this point a question arises: In the leukemic states, does hyperplasia occur in the normal sites of origin of these various cells or is there in addition a reversion to embryonic conditions in which extramedullary hematopoiesis occurs? It seems certain that the

latter condition does exist in myeloid leukemia, where, according to Naegeli,⁷ not only can an active hyperplasia develop normally in the bone marrow, but there is extensive extramedullary myelopoiesis in the connective tissues of the body. He believes that these secondary foci in the spleen are responsible for its increased size as well as an accumulation of cells gathered from the blood stream.

There is further evidence to favor the view that in leukoses variation in the origin of leukocytes is the rule rather than the exception. In lymphatic leukemia, autopsy generally shows a terminal lymphoid proliferation in the bone marrow. There is some evidence that in monocytic leukemia the monocyte, regardless of where it arises under normal conditions, has its origin chiefly in the bone marrow. A number of the reported cases have terminated as typical myeloblastic leukemias. The formation of secondary foci has been considered as a metastasis starting from the bone marrow, lymph tissue or monocytic centers.¹⁵ Others do not consider this extramedullary hyperplasia a metastatic condition but rather "the activity of the reticulo-endothelium widely scattered throughout the body." Under the proper stimulus this undifferentiated mesenchymal tissue becomes active, causing a reversion to embryonic blood formation.¹⁶

Since anemia and hemorrhagic tendencies are almost invariably sequelae of the leukemic states, some discussion of erythropoiesis and thrombopoiesis should be given. In addition, some explanation should be made to emphasize the unfortunate relationship of the leukemic process to erythropoiesis.

According to Doan's¹⁷ studies, red cells begin their maturation in gelatinous bone marrow and have their immediate origin from the inside lining of the closed vascular sinusoids. A sluggish blood flow, low oxygen tension, and collapsed sinusoids favor erythropoiesis.¹⁸ The endothelial lining of these blood vessels swells and gives rise to megakaryoblasts, which in turn eventually form mature erythrocytes. These corpuscles are forced into the blood stream as the blood passes from the vascular bed of the marrow to the peripheral circulation. White cells are formed extravascularly and pass into the blood vessels by their own motility. Granulopoiesis is said to begin when the collapsed sinusoids dilate and is more active in areas richly supplied with blood.^{17b} Doan^{17b} and Sabin¹⁸ state that this difference in time and location for erythropoiesis and granulopoiesis necessitates a functional division of the two processes. For this reason, an excessive stimulation of myeloid tissue such as in myelosis, resulting in a flushed vascular bed, may produce an unfavorable environment for normal red cell formation. This condition plus an actual mechanical obliteration of erythropoietic tissue by excessive myeloid hyperplasia may be a predisposing factor for the inevitable anemia accompanying a majority of the leukemias.

LEUKOBLASTS

A differentiation of the three types of leukoblasts on morphologic criteria offers a difficult cytologic prob-

lem. The myeloblast, lymphoblast and monoblast present many similarities. There is little difference in size and morphology at first glance. All have a round, red purple nucleus with a clear, deeply staining nongranular blue cytoplasm. Naegeli⁷ believes that the myeloblast may be distinguished from the lymphoblast chiefly on fine nuclear criteria. According to his concept, the nuclear chromatin is finer and more homogeneous than in the lymphoblast, the chromatin of which has a coarse arrangement and appears dense at the edges of the nucleus, giving evidence of a definite nuclear membrane. Another point of distinction is the number of nucleoli; myeloblasts contain from three to five pale nucleoli, while lymphoblasts show a smaller number, generally from one to three. The presence of a definite perinuclear zone is characteristic of the lymphoblast and is rarely, if ever, found in typical myeloblasts. Obviously, these aids to distinction are inadequate and final differentiation depends more on association of the indefinite cell types with the more easily recognized cells, which belong to the same series.

With regard to the monoblast, there are differences of opinion as to whether it can be definitely distinguished from the other two leukoblasts. It is agreed that it cannot be distinguished by ordinary staining methods. Naegeli⁷ makes no effort to isolate this cell type. He offers evidence that monoblasts and monocytes are myeloid in nature by the similarity of nuclear structure, the characteristic maturation of the nucleus in its basophilic chromatin structure, the segmentation of the monocytic nuclei occurring with age, and the positive oxidase, peroxidase dopa reactions and positive lipid granule stains.

Other investigators¹⁹ definitely classify monocytes into a separate group of leukocytes. Their conclusions have resulted from supravital staining technique and their distinction between the three leukoblasts rests on the size, position and structure of mitochondria and neutral red vacuoles. Naegeli⁷ states that these supravital changes have not been substantiated by other investigators (Hall, Newer, Maximow, Bloom).

The oxidase reaction in the three primary leukoblasts is negative, since none contain granules. This test, devised by Graham²⁰ and Goodpasture,²¹ and later modified by Sato and Yoshimatsu,²² is, however, of great diagnostic value in a differential diagnosis of acute lymphatic and myeloid leukemias. When this test is positive, a diagnosis of myeloid leukemia can be made with fair certainty. A negative test, however, does not rule out the possibility of a predominance of myeloblasts. In this instance other diagnostic aids must be employed, i. e. histologic changes and the indophenol blue synthesis²³ test, which is positive in myeloid leukemia and negative in lymphatic.

Stain for three minutes in a mixture of solution A and B (one part of A plus four parts of B). 3. Counter stain for three minutes with Giemsa's stain (Gruhlner) and examine the preparation while immersed in water. Myeloid granules and myeloblasts stain blue. Lymphocytes do not stain. Monocytic granules stain blue. Solution A. One hundred cc. of 1 per cent alpha naphthol in physiologic solution of sodium chloride to which is added 1 cc. of tenth normal sodium hydroxide. Solution B. A 1 per cent solution of para dimethyl paraphenylenediamine base (Merck) in physiologic solution of sodium chloride.

There is a wide difference of opinion concerning the oxidase reaction in monocytic leukemia. Until the disease has been studied more fully and proved a separate entity, this test is of little diagnostic aid. Naegeli⁷ states that mature monocytes are peroxidase positive and does not recognize a monocytic type of leukemia. His description of the condition is a "monocytoid phase of myeloid leukemia."

We have studied carefully the cases of monocytic leukemia in the Hematological Registry, which is, no doubt the largest collection existing, and have noted the large percentage of well studied cases that eventually terminate as definite myeloid leukemia. This would indicate, at least, that under leukemic conditions the monocytic cell is identical with the myeloblast.

THE CHRONIC LEUKEMIAS

Chronic myelosis and lymphadenosis are diseases of middle and old age and are rare in young people. The onset of chronic leukemia is insidious and the duration variable, the usual course being from two to five years. A physician seldom sees chronic leukemia in its incipient stages, the disease is usually well established before the patient seeks medical aid.

In chronic myelosis the usual complaints are a feeling of fullness and pressure in the epigastrium (due to the splenic tumor), disturbances of digestion, pain in the left side of the abdomen, fatigue and pallor. The splenic tumor may fill half the abdomen. Other clinical manifestations are disturbances in sight and hearing, pains in the gums, diarrhea, dyspnea and palpitation of the heart. The bones are often sensitive to pressure. The blood picture is characterized by high leukocyte counts, usually from 100,000 to 400,000, counts as high as 1,000,000 have been found. The criterion of a leukemia, however, is not the number of white cells but the type of white cell present. In myelogenous leukemia the cells of myeloid origin usually constitute about 95 to 99 per cent of the cells, with the neutrophilic myelocyte as the predominating abnormal cell type. Myeloblasts may be present in from 1 to 3 per cent in the early stages, usually increasing later or in a transition to an acute form. Naegeli⁷ states "The most important feature of a leukemia is not the high leukocyte count but the fact that the blood shows all cells of myeloid tissue so that really only quantitative differences exist between leukemic blood and normal bone marrow." The blood is viscous, possesses oxidase and peptic ferments and gives a typical positive indophenol blue reaction. There is moderate to severe anemia, and the platelets are usually increased in number.

In chronic lymphatic leukemia the patient usually visits the physician because of a painless but progressive swelling of the lymphatic glands, especially the cervical, axillary and inguinal glands. The spleen is usually enlarged. There are infiltrations and hemorrhages in the retina, and sometimes infiltrations into the skin.

The hematologic picture shows a leukocyte count, usually of several hundred thousand, with small lymphocytes predominating, even 99 per cent. Smudge forms are constant. The platelets are almost always decreased. The red cell count and hemoglobin are not decreased in the first stages, but, as the disease progresses, moderate or severe anemias occur. The blood shows no oxidase or peptic ferments and a negative indophenol blue synthesis.

THE ACUTE LEUKEMIAS

Since Virchow first described leukemia there has been a constant evolution of ideas concerning its histologic and hematologic manifestations. It is one of the oldest of known blood diseases, yet knowledge of its etiology has advanced little since Ehrlich's time. A long list of imposing names is linked with the subject of leukemia. Sherrer,⁸ soon after its discovery, believed the spleen to be a genetic factor in one type of leukemia and therefore proposed two kinds of leukemia: splenic and lymphatic. Newman⁹ found bone marrow changes in the splenic type and thus established myelogenous leukemia. Ehrlich⁵ gave a classification and propounded the dualist theory for the origin of leukocytes. Naegeli⁷ was the first to recognize and describe myeloblastic leukemia. Before this time these cells were thought to be lymphocytes. Furthermore, he exploded the theory of a transition from myeloid to lymphatic leukemia. He states that "all acute myeloid leukemias arise as myeloblastic, and the chronic form, in exacerbation and before death, eventuates into secondary myeloblastic leukemia." Kundrat⁶ was one of the first to recognize that leukemia affected not only a single organ but the entire body. Meyer and Heneke⁶ (1907), Naegeli and Fabian⁶ (1907) and Schridde⁶ (1908) proved that extramedullary metaplasia of myeloid tissue occurs in both physiologic and pathologic conditions.

The acute form of leukemia is a disease of the young, occurring most frequently in individuals under 25 years of age. For many years acute leukemias were considered lymphatic in nature. It is now generally recognized that acute leukoses in adults are myeloid in type. Naegeli⁷ emphasizes this point: "I doubt whether a certain peracute lymphatic leukemia exists in an adult." Certainly no convincing cases have been reported within the last ten years. This condition in children, however, is almost invariably lymphatic in origin.

Clinically, there is a sudden onset and a rapidly fatal course. When a patient presents the clinical and hematologic picture of an acute leukemia and lives longer than six months, the condition is probably an acute exacerbation of a chronic process that has existed for a long period of time with no noticeable symptoms. Into this class fall many of the reported cases of acute leukemia. Too much stress should not be made, however, on the duration of illness as a distinction between the chronic and acute forms.

Acute myeloblastic and lymphatic leukemias are identical clinically and symptomatically. The patient generally becomes ill with dramatic suddenness and exhibits all or a few of the following conditions: headache, extreme prostration, pain in the joints, a necrotic gangrenous gingivitis, bone pains, retinal changes, vomiting, diarrhea, hemorrhages, and severe and progressive anemia. Generalized glandular enlargement and increase in size of spleen and liver are variable physical manifestations, whereas cervical adenopathy is of more frequent occurrence. In some instances these characteristic changes are absent and the disease may appear diagnostically obscure, simulating sepsis or any variety of acute conditions.

Acute myeloblastic leukemia usually presents the following blood picture: 1. A subleukemic leukocyte count, if taken during the early stages of the disease, which ranges from a few thousand to 30,000 or 40,000 per cubic millimeter. The count may rise rapidly to

100,000 or slightly higher, but rarely to the figures found in untreated chronic forms. 2 A marked anemia, which in the later stages presents a microscopic picture of pernicious anemia with hyperchromic cells, polychromatophilia, normoblasts, megaloblasts and marked variation in size and shape. 3 A marked reduction in the number of platelets, which explains the frequency of the hemorrhagic diathesis accompanying acute leukemias. 4 A preponderance of myeloblasts, which on superficial examination appear to belong to the lymphocytic series. Close examination will finally reveal, however, the intermediate faintly granulated promyelocyte, the presence of which in sufficient numbers makes the diagnosis a certainty. In some cases neutrophilic myelocytes are present in large numbers. In addition to these predominant cell types there are found frequently a few mature neutrophils.

In some instances the microscopic picture may consist entirely of myeloblasts, micromyeloblasts and mature segmented neutrophils without any of the other intermediate forms found in the normal maturation cycle. Naegeli⁷ calls this phenomenon "hiatus leucæmicus" and considers it an infallible sign of an acute phase. Warren,²⁴ in 1929 in a review of the literature and a report of twenty-eight of his own cases, found only eighty-five from 500 cases in the literature that could be classified without criticism as true examples of acute myeloblastic leukemia. Ordway and Gorham¹⁰ give the following postulates for substantiating the diagnosis of this condition:

- 1 An aleukemic or subleukemic stage
- 2 An acute downward course with death usually ensuing within from one to four months
- 3 The characteristic blood picture of myeloblasts, myelocytes and the transition forms between the two
- 4 The typical gross and histologic changes in the liver, spleen, bone marrow and lymph glands
- 5 The specific proof of myeloid elements by enzyme reactions

The clinical changes and blood picture of acute lymphatic leukemia are identical with myeloblastic leukemia with the exception of the predominant cell type involved. The large lymphocyte and lymphoblast predominate. The azure granulation characteristic of normal lymphocytes is absent, according to Naegeli's⁷ observations, thus fortunately preventing confusion with granulated promyelocytes of the myeloid series. As a rule, the differential diagnosis between these two types of leukemia presents difficult problems. The diagnosis is easy if in myelosis the characteristic premyelocytes and myelocytes are present in sufficient numbers to give a peroxidase positive reaction. Otherwise differentiation rests on the obscure morphologic differences between myeloblasts and lymphoblasts or the more exact indophenol blue synthesis. Occasionally myelocytes, sometimes as high as 10 per cent, appear in lymphadenosis to confuse the diagnostician further. These are called "irritation myelocytes" by Pappenheim and appear only in the early stages of the disease.¹⁶ These myelocytes are typically mature with no accompanying promyelocytes, as seen in myeloblastic leukemia.

It is difficult to separate the acute leukoses on a clinical basis. An extensive glandular enlargement, however, favors the diagnosis of lymphadenosis, but its absence does not exclude myelosis.

One of the diagnostic difficulties relative to acute lymphatic leukemia is its confusion with acute benign lymphadenosis or infectious mononucleosis. Their similarity in the early stages is a diagnostic pitfall for both experienced clinicians and veteran hematologists. Both are diseases of childhood or young adults. Both are characterized clinically by an acute onset, high fever, generalized adenopathy and sore throat of the ulcerative type, and hematologically by a relative and absolute lymphocytosis. It is generally agreed that the predominating lymphoblast appearing in both conditions cannot be distinguished morphologically with certainty, although Downey and McKinlay²⁵ published in 1923 a report of nine cases in which they gave a criterion for separating these cell types.

There are, however, some striking differences in the two conditions. Infectious mononucleosis is milder in its clinical manifestations, running a benign and harmless course. Red cell and platelet changes are never sequelae of this disease. As a general rule, the leukocyte count is lower than in acute lymphatic leukemia.

It is safer to be cautious and follow the rule that a diagnosis of acute lymphatic leukemia is dangerous on morphologic grounds alone and in the absence of red cell and platelet reductions.

A discussion of the acute leukemias would not be complete without introducing the subject of a new type of leukemia, reported first by Reschad and Schilling-Torgau² in 1913. They discovered what they consider a leukemia of the monocytic series of leukocytes in which the predominant cell type is a typical "transitional" cell or monocyte. Other authors²⁶ separate the development of the monocyte from the other leukocytes. It is interesting to note what the leaders of the monophyletic and dualistic schools reported on examination of a smear sent to them from this case. Pappenheim, the leader of the monophyletic theory for the origin of leukocytes, reported "a selective, highly pronounced monocytosis characterized by the presence of genuine transitional forms of the lymphatic type." In contrast to this view, Naegeli, a strict dualist, in a recent correspondence, classified this type of leukemia as a "monocytic leukocytosis" or as an atypical type of myeloid leukemia. Fleischmann²⁷ in 1915 reported the second case of monocytic leukemia. He is in agreement with Naegeli, since he believes that his case changed to a myeloblastic leukemia in the terminal stages. This view is likewise upheld by Ewald, Frehse and Hennig,²⁸ Alder²⁹ and others. On the other hand, Dameshek,¹¹ Merklen and Wolf,¹³ Sydenstricker and Phinzy,¹⁹ Clough,³⁰ Lawrence, Josey and Young³¹ and a majority of the American authors are inclined to support the conception that this third type of leukemia exists and that the monocyte has an independent and separate cycle of maturation.

24 Warren S. L. Acute Leukemia. A Review of the Literature and of Twenty Eight New Cases. Am. J. M. Sc. 178: 490 (Oct.) 1929.

From a review of thirty-two published cases in England and America and sixteen unpublished cases on file in the Hematological Registry, it may be said that, in general, monocytic leukemia differs little clinically from the other acute leukemias other than in age limits, which range from 1 to 78 years and average around 40 years. It occurs in males about twice as frequently as in females. The onset is generally insidious, with fever, malaise and marked pallor. Gingivitis of the ulcerative type is found in about half of the cases. Bleeding and petechial hemorrhages are prominent in the histories. Enlargement of lymph glands is a variable physical finding. The duration of the disease varies from ten weeks to two years. The course is progressively downward, with sequelae of marked anemia, bleeding and petechiae. The leukocytes range from 600 to 320,000 per cubic millimeter. Red cells and platelets are markedly decreased in the last stages of the disease.

The diagnosis of this type of leukemia rests entirely on the morphologic examination of the stained blood cells. The cell type is the fully developed, mature monocyte and in some cases the histiocyte. Many authors believe that this cell cannot be identified with certainty without a confirmation with supravital stains. As yet no agreement exists as to whether monocytic leukemia is a disease entity. Until the points at issue in regard to the origin of the monocytes are settled, an attempt to classify this condition as chronic or acute would be difficult.

THE ALEUKEMIC STATE

In all types of leukemia, especially the acute forms, the process may undergo at one time or another an aleukemic phase in which the leukocytes drop below the normal level. This phase cannot be distinguished clinically, organically or histologically from the more typical leukemic conditions. The term "aleukemia" is misleading. The condition probably should be considered a leukopenic phase of the existing leukemic process. The reason for the disappearance of the leukocytes in the peripheral blood is shrouded in mystery. This phase may occur at any stage of the disease or the patient may be seen by the physician for the first time with a marked leukopenia, a severe anemia of the hyperchromic megaloblastic type, and a decided decrease in platelets with the resulting hemorrhagic diathesis. In this case the condition becomes of special importance diagnostically.

If the condition is myeloid in nature, a correct diagnosis is more easily made. According to Pinkerton,³² a comparative study of five cases of aleukemic myeloid leukemia shows a "diversity of clinical symptoms" but a marked anatomic and postmortem similarity. As a rule, patients suffering from this condition show an enlarged spleen, a myeloid hyperplasia of lymph nodes and other organs and a hyperplastic bone marrow in addition to leukopenia, progressive anemia and thrombopenia. The predominant cell type is the myeloblast when this phase occurs in acute myelosis and the myelocyte when the patient is suffering from the chronic form. Thus, in this instance the differential count with its high percentage of immature cells, the severe primary anemia blood picture, hemorrhagic tendencies, and an enlarged spleen make one suspicious of leukemia despite the low leukocyte count. It is true that in many instances there is no splenic or glandular enlargement.

At any rate, a diagnosis cannot be made with assurance until the leukocytes rise to leukemic levels or the biopsy and autopsy finding of myelosis clears up uncertainty.

In aleukemic lymphadenosis, which is said to be more prevalent than the myeloid type, the diagnosis is even more difficult. The signs and symptoms are those of acute leukemia. Gross hematologic changes are identical with those of aleukemic myelosis: leukopenia, anemia, thrombopenia. The differential count alone differs. In the microscopic picture the lymphoblast and mature lymphocyte predominate, depending on the acuteness or chronicity of the underlying pathologic changes. In the latter, it is generally impossible to distinguish the condition from a typical aplastic anemia, in which again there are marked thrombopenia, neutropenia and erythropenia. There are only a few fine points of distinction. In aplastic anemia the physical changes are entirely negative, the anemia is a normocytic, normochromic type with no normoblastic regenerative changes, and the bone marrow is typically aplastic. In aleukemic lymphadenosis there is in some cases a lymphoid enlargement and hyperplasia, and the anemia is more often of the hyperchromic, normoblastic and megaloblastic type. There is frequently a marked variation in size and shape of the red corpuscles and, as a rule, the platelets do not reach the low levels found in aplastic anemia. As in the myeloid type, diagnosis may depend entirely on biopsy and autopsy observations unless the patient survives this depression phase and eventuates into a typical leukemic state.

Not only is it difficult to distinguish the various types of aleukemia from one another and from aplastic anemia, but they are easily confused with certain stages of granulopenia, Vincent's oral sepsis, the hemorrhagic states, and pernicious anemia.

Typical acute cases of granulopenia are not hard to differentiate, since the neutropenia is more marked and progressive in this condition and the red cells and platelets are only slightly affected. In those cases of granulopenia, however, which show the erythropenic-thrombopenic syndrome, one encounters the same diagnostic difficulties as in separating the aleukemic states from the aplastic anemias. Only one point of difference exists: the anemia associated with granulopenia is generally of secondary type until the terminal stages, when it becomes inseparable from aplastic anemia.

Vincent's oral sepsis is confused with aleukemic states only temporarily and clinically. Oral sepsis and Vincent's ulcerative lesions may be the first clinical symptoms to bring a leukemic patient to the physician's attention. A blood examination quickly reveals the more serious nature of the condition.

On the other hand, profuse bleeding or petechial hemorrhages may be the first outstanding manifestation of aleukemic leukemia leading the physician to suspect a simple purpuric condition. Careful hematologic and physical examinations will soon reveal the error in diagnosis, since the purpuric states show a normal leukocyte count and secondary anemia only when hemorrhages have become of such severity as to lead to definite loss of blood volume. Platelet counts, time of bleeding and coagulation will serve to aid in the differential diagnosis.

Aleukemic leukemia and pernicious anemia are similar only in the type and degree of anemia, since both show a hyperchromic erythrocyte picture. Except in the terminal stages of pernicious anemia, the leukocyte count is normal or only slightly depressed, the differ-

32 Pinkerton, Henry. Aleukemic Leukemia and Typical Leukemoid Conditions. Arch. Path. 7: 567 (April) 1929.

ential count is essentially normal and the platelets are little affected. The color of the skin and sclera, gastric changes and response to liver therapy will soon rule out or confirm the diagnosis of pernicious anemia.

CONCLUSIONS

1 There still remains no unanimity of opinion relative to the origin of white blood cells, but it seems probable that under normal conditions myeloid cells arise mainly from the bone marrow and lymphoid cells from the lymphoid glandular system, including the spleen.

2 It is virtually impossible to distinguish between the various types of leukoblasts with ordinary staining methods, or even with vital staining.

3 Cases of chronic leukemias can be diagnosed easily as well as acute forms provided the total white cell count is definitely increased with a preponderance of blast cells.

4 The leukemic states in which the total number of white cells is normal, or below normal, offer considerable difficulty in diagnosis both clinically and hematologically and are apt to be confused with various leukopenic diseases.

5 The most reliable criterion for the diagnosis of any leukemia is a preponderance of immature cells regardless of the total number. Studies on a large number of cases of monocytic leukemia that are filed in the Hematological Registry indicate that the chief cell type has its origin in the bone marrow and adds further evidence that monocytic leukemia is but an atypical phase of myelogenous leukemia.

LEUKEMIA

ITS DIAGNOSIS AND TREATMENT

NATHAN ROSENTHAL, M.D.

AND

WILLIAM HARRIS, M.D.

NEW YORK

Of the serious disorders of the hematopoietic system, leukemia is most frequently encountered. Although usually associated with splenomegaly or lymphadenopathy, by the presence of which it is readily differentiated, leukemia may be confounded with other conditions characterized by anemia, infection, purpura or lymphadenopathy. The difficulty in diagnosis is due to the many variations that may occur both in the clinical picture and in the laboratory observations.

Leukemia has heretofore been regarded as a disorder characterized by a persistent increase in the number of white blood cells. According to the present conception of the disease, however, an increase in the number of white cells is not an essential diagnostic factor.

The present study comprises observations on 455 patients in Mount Sinai Hospital and in private practice during the past fifteen years, as classified in the accompanying table.

CLASSIFICATION OF MATERIAL

The cases observed were divided into two groups, namely, acute or chronic. Patients who lived three

months or less were regarded as suffering from acute leukemia (38 per cent of our material), those who survived longer than three months were included in the chronic group (62 per cent). The cases were further classified according to the predominance of certain cells, as (1) myeloid leukemias (66.7 per cent), (2) lymphatic leukemias (27.6 per cent), and (3) monocytic leukemias (1.9 per cent). It is interesting to note that these percentages are identical with the percentage of the neutrophils, lymphocytes and monocytes present in normal blood.

For practical purposes, cases in which there were 15,000 leukocytes or less were considered leukopenic, those with a larger number of leukocytes were classified as leukocythemic. The number of leukocytes in our series varied from 400 to more than 1,000,000. The classification, therefore, utilized in this paper, i. e., leukopenic leukemia of an acute or chronic variety, is an arbitrary one and is not based on actual differences in the fundamental nature of the disease.

BLOOD PICTURE

The diagnosis of leukemia can usually be made from the blood count and an examination of the blood smear.

The presence of a persistent relative or absolute increase in the number of mature or premature white blood cells constitutes the important characteristic alteration in leukemia. The premature cells are the myelocytes and their nongranular precursors or myeloblasts, the premature lymphocytes or lymphoblasts and precursors of the monocytes or monoblasts. Mitotic myeloblasts and anutotic myeloblasts and lymphoblasts may occasionally be present.

The type of premature cell usually varies with the duration of the disease. Cases of acute leukemia are characterized by the presence of the more premature types of cells, particularly the myeloblasts, lymphoblasts and monoblasts, while chronic varieties have a tendency to display more mature types, such as polymorphonuclear neutrophils and myelocytes in the myeloid leukemias, and lymphocytes in the lymphoid leukemias.

The hemoglobin and the number of red blood cells are usually reduced in acute leukemias. In chronic types, anemia may be absent or only moderate at the onset. The anemia is hypochromatic, with a color index that varies from 0.5 to unity. Nucleated red cells are usually present.

The blood platelets present marked variations in leukemia. In the early stages of chronic leukemia they are normal, but they are usually profoundly reduced in acute varieties or in acute exacerbations of the chronic forms. In some of our cases of "polynuclear-celled leukemia" that followed polycythemia, a thrombocythemia, or persistent increase of the blood platelets from 500,000 to 2,000,000 per cubic millimeter occurred.

Occasionally, a typical leukemic blood picture was accidentally found in cases that were entirely asymptomatic and later showed symptoms of the disease.

SYMPTOMATIC VARIATIONS

Weakness and fatigue are common and persistent symptoms in leukemia. Abdominal distress, caused by enlarged viscera or lymph nodes, is a usual complaint. Frequently pain and ulceration in the upper part of the respiratory tract may be observed at the onset of the disease. Purpuric manifestations or uncontrollable bleeding, such as epistaxis, bleeding gums or persistent hemorrhages following a surgical procedure, may be the

From the Medical Department and Laboratories of the Mount Sinai Hospital.

Read before the Section on Radiology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

first evidence of the leukemic state. Gastro-intestinal hemorrhage is less frequent. Pallor, cough, arthralgia, myalgia and loss of weight may occur during the course of the disease.

Enlargement of the spleen is usually observed in myeloid leukemia, enlargement of the lymph nodes particularly in the cervical region, in lymphatic leukemia. However, both the spleen and the lymph nodes may be involved in either type of leukemia. In one case of lymphatic leukemia there was an enlargement of the spleen without peripheral adenopathy. In acute leukemia, however, the splenomegaly and lymphadenopathy are less marked.

DIFFERENTIAL DIAGNOSIS

A typical case of leukemia, either acute or chronic, is usually differentiated by the presence of an increased number of white blood cells as well as mature or pre-mature leukocytes. However, difficulty in diagnosis

Classification and Frequency of Various Types of Leukemias

	Percentage of All Cases	No. of Cases		Total No. of Cases
		Males	Females	
Myeloid Leukemia

may be encountered in cases of leukopenic leukemia in which the number of leukocytes is normal or profoundly reduced. Such cases, when admitted to the hospital, are sometimes diagnosed as pernicious anemia, purpura haemorrhagica, agranulocytosis, subacute endocarditis, splenic anemia or other disorders.

Anemia—After the anemia has developed, it becomes progressive and responds only temporarily to the usual therapy for secondary anemia. If the color index is relatively high and nucleated red cells are present the leukemia may simulate pernicious anemia. The characteristic macrocytosis of pernicious anemia is not observed, but the presence of myelocytes or myeloblasts is indicative of a leukemic condition.

All cases of chronic, progressive anemia with splenomegaly require continued and careful study of the blood. Leukopenic leukemia may simulate splenic anemia, hemolytic icterus, subacute endocarditis, Gaucher's disease and thrombosis of the splenic vein. Here again the presence of myelocytes or myeloblasts with a leukopenia or even with a normal number of leukocytes should provoke the suspicion of leukemia.

In rare instances the blood pictures of aplastic anemia and of leukopenic lymphatic leukemia may be identical with respect to the profound anemia, thrombocytopenia, leukopenia and relative lymphocytosis. In such cases the presence of splenomegaly or lymphadenopathy may indicate leukemia. In some cases the correct diagnosis can be made only by means of a biopsy on the bone marrow, which may reveal the lymphoid metaplasia of the rare medullary lymphatic leukemia or the hypoplasia of aplastic anemia.

Purpura—Bleeding from the gums or nose or into the skin as in purpura haemorrhagica, may occur at the onset in practically all forms of leukemia, as a matter of fact, this may be the only symptom for a long time. Severe anemia, due to considerable loss of blood may supervene as the disease progresses. This bleeding tendency in leukemia is due to an associated deficiency of blood platelets, as in primary thrombocytopenic purpura haemorrhagica. It differs from the latter however, in its differential blood count, which is typical of leukemia.

A striking example of this type of case was observed in our series. The patient was treated for epistaxis, bleeding from the gums, purpura and a progressive anemia. The leukocytic count was normal, but the abnormal cells in the spread had been overlooked. On the basis of the good results obtained from splenectomy in cases of purpura haemorrhagica, the patient was admitted to the hospital for splenectomy. Careful examination of the blood revealed that, in addition to a marked diminution in the number of blood platelets and a severe anemia, a characteristic increase had occurred in the number of myelocytes and myeloblasts. A diagnosis of myelogenous leukemia was made and splenectomy was not performed.

In two similar cases of our series, splenectomy produced no increase in the blood platelets. The purpura persisted and a leukocythemic type of leukemia developed.

In the acute type of all the leukemias, and in the late stages of the chronic forms, the number of blood platelets is reduced, but the hemorrhagic tendency does not correspond with the diminution of the platelets. Patients who have the same marked numerical diminution in blood platelets may react differently. In some there may be no signs of bleeding throughout the course of the disease, others may have hemorrhages of varying severity into organs such as the eyes, brain and middle ear, or from the mucous membranes. In one instance a puncture of the ear was followed by bleeding for twenty-four hours, which was controlled by a blood transfusion. In some cases the epistaxis and gingival bleeding may lead to exsanguination.

Infection—Secondary infection is not unusual in leukemia. It may obscure the underlying condition, so that it resembles grip, subacute bacterial endocarditis, or agranulocytosis. Among the severe complications, pleurisy, pneumonia and alveolar abscess may be mentioned. Bacteremia, early or late in the course of the disease, was observed in about 2 per cent of our cases.

Fever may be present in chronic as well as in acute cases, but it is not necessarily the result of frank supuration. It may disappear with the improvement in the general condition, following blood transfusions or radiotherapy.

Ulcerations of the mucous membranes are very frequent in acute leukemias. The gums may be involved, producing a considerable amount of pain and swelling,

particularly in the lower jaw. At times extraction of teeth may be followed by a marked exacerbation of the entire process—a circumstance that often leads to the differentiation of the leukemic condition. In cases of leukemia with profound diminution of the number of leukocytes below 2,000 per cubic millimeter, necrotizing pharyngitis may simulate agranulocytosis. However, the presence of anemia, a hemorrhagic diathesis, and myeloblasts in the blood smears indicate the presence of leukemia rather than of agranulocytosis.

Lymphadenopathy—Leukemia should be differentiated from the various conditions associated with localized or generalized lymphadenopathy. As a rule, the blood picture is sufficient to differentiate leukemia from Hodgkin's disease or lymphosarcoma. Occasionally a nonspecific lymphadenosis may persist for many months before a true leukemic blood picture is evident.

Infectious mononucleosis (lymphocytosis or monocytosis) may be mistaken for leukemia. The clinical course in this disease, however, is usually typical of a benign condition—fever, sore throat, absence of anemia (either clinical or hematologic), and transient lymphocytosis or monocytosis. The positive heterophile antibody reaction is often helpful in excluding leukemia.¹

ATYPICAL LEUKEMIAS

Atypical leukemias are regarded as varieties of the well known forms or as rare cases. Chloroma, or chloroleukosarcoma, is one of the most interesting of these types. Essentially this is a myeloblastic leukemia with subperiosteal infiltrations that involve the orbit and cause exophthalmos. In the gross, the deposits have a typical green coloration.

In a small percentage of myeloid leukemias—usually of the chronic variety, although rarely of the acute—a generalized osteosclerosis of the bone marrow was observed. In some of our cases this was verified during life by means of a biopsy on the sternal bone marrow. Although no special blood changes characterize this particular form, most of our cases were leukopenic and myeloid. Cases of this type may occasionally be of long duration, eighteen years in one of our series.

Certain unusual variations of lymphoid leukemias may be mentioned, such as the splenic, medullary and plasma cell types. In the splenic variety the principal finding is a splenomegaly without a peripheral lymphadenopathy, it may resemble myeloid leukemia. In the medullary form the spleen and lymph nodes are not palpable. Sternal biopsy may be necessary to establish the underlying lymphoid metaplasia. Plasma cell leukemia is very rare,² only one case having been observed in our series.

There is also an extremely rare form of aleukemic leukemia in which the blood picture is nonleukemic but the lymph nodes (on biopsy) present the typical changes observed in chronic lymphatic leukemia.

Cases of splenomegaly have likewise been described in which the chief changes are marked leukocytosis with predominance of mature eosinophils³ or of polymorphonuclear neutrophils.⁴ While such cases are not

usually classified among leukemias, their course and symptoms are somewhat parallel. A similar eosinophilia may be present in Hodgkin's disease.⁵ The polynuclear cell leukemias, on the other hand, bear a close relationship to polycythemia. It is not unusual to find marked polynucleosis in the early or late stages of polycythemia. Subsidence of the polycythemia is not infrequently associated with the development of severe anemia, accompanied by either marked polynucleosis or myeloid leukemia (so-called erythroleukemia of Di Guglielmo⁶).

INCIDENCE

Age—Leukemia may occur, with varying frequency, at any time during life. In acute myeloid leukemia the largest percentage occurred between the ages of 20 and 29, in the chronic variety the disease was encountered most frequently between the ages of 30 and 39. These observations agree with those of Minot, Buckman and Isaacs.⁷ Chronic lymphoid leukemia was observed most frequently between the ages of 50 and 69.

Sex—Our series revealed a predominance of the disease in males, 277 cases occurring in males and 178 cases in females, as shown in the table. In the two sexes the course of the disease was identical.

TREATMENT

Because of the limitation of knowledge concerning the etiology of leukemia, no specific remedy is known, the treatment therefore is essentially symptomatic. The ends to be accomplished are (1) improvement of the general condition and affording comfort by rest, diet and sedatives, and (2) increase of strength and efficiency by blood transfusions and roentgenotherapy.

The literature is replete with suggestions regarding effective medicinal measures. Among the many therapeutic substances that have been advocated are lead, sulphur, malarial inoculations, embryonic extracts and arsphenamine. Some of these measures (neoarsphenamine, malaria, fetal liver extract and raw fetal liver) have been employed in our series without satisfactory results.

Blood transfusions may be employed to combat the anemia and to deter the leukemic process. In some instances the anemia and hemorrhagic diathesis are improved after the first or second blood transfusion, subsequent transfusions may not be efficacious.

Transfusions frequently prolong the patient's life and may even induce a remission. This was strikingly demonstrated in the case of a child, aged 5 years, who, when first seen, had a severe anemia, with marked leukopenia with numerous myeloblasts. While under observation the patient became extremely pale and stuporous, a blood transfusion was given at that time, which resulted in so marked an improvement in the clinical condition that the child survived about one year after the onset of the disease.

Splenectomy in leukemia should be discouraged. As a rule the operation is fatal, although the patient may live about three months—rarely longer. In the questionable stage of chronic myelogenous leukemia⁸ the opera-

tion may be tolerated better. In two cases of leukopenic myeloid leukemia in our series, splenectomy was followed by a leukocytic myeloid leukemia. Since leukemia is a disease of the entire hematopoietic system, it is unreasonable to expect any constant alteration in the general condition by removal of only one of the affected organs. In one case of claking of the splenic artery,⁹ surgical procedure induced no improvement.

Conservatism should be the keynote of treatment of leukopenia. Iron and arsenic and liver extract are well tolerated and apparently have some immediate beneficial effect in maintaining the hemoglobin at a constant level. The anemia, however, tends to be progressive and transfusions are then necessary to increase the hemoglobin and to improve the general condition. In these cases radiotherapy is of no value in reducing the size of the spleen. Furthermore, it is definitely contraindicated in marked leukopenia and in such cases may even be followed by untoward effects such as secondary infection, necroses and hemorrhage.

The cases in which treatment is most availing are the chronic myelogenous and lymphatic leukemias of the leukocytic variety. In these the aim should be to reduce the number of white blood cells and to increase the hemoglobin and red blood count. Although this may not necessarily prolong life, it will usually increase efficiency and well being.

Reduction in the number of white blood cells or leukocytolysis, as suggested by Aubertin,¹⁰ may be accomplished by several methods, namely, (1) chemical, (2) biologic or (3) physical.

1 *Chemical Method*—(a) Arsenic. Prior to the extensive employment of roentgenotherapy, arsenic was frequently utilized in the treatment of leukemia. Its use was popularized by Bramwell,¹¹ who reported the first apparent remission in leukemia. Subsequently the enthusiasm for arsenic waned but recently it has been advocated in larger doses by Forkner.¹² The best results with this drug are obtained in a few selected cases of chronic myelogenous leukemia. It has practically no influence in chronic lymphatic leukemia. To be effective, solution of potassium arsenite should be given in large quantities. The initial dosage of five drops three times a day should be gradually increased to ten drops three times a day. It may not produce improvement in symptoms. Occasionally it causes anorexia and loss in weight. It can be employed advantageously between courses of roentgen treatment.

(b) Benzene. Benzene, introduced by von Koranyi,¹³ in the treatment of this condition, is poorly tolerated and rarely effective. Repeated use of this drug in some of our cases was followed by no response.

2 *Biologic Method*—Leukocytolytic substances have been demonstrated in leukemia by Capps and Smith.¹⁴ Lindström¹⁵ was able to produce an antileukocytic

serum from leukemic white blood cells. These investigators used such serum in cases of leukemia and obtained only transitory beneficial response.

3 *Physical Method*—Radiotherapy. This is the most satisfactory form of treatment. There is no doubt that roentgenotherapy is of the greatest therapeutic value in chronic myeloid and chronic lymphoid leukemia. Since the first case was so treated by Senn¹⁶ in 1903 it has been used with increasing and justifiable popularity. Radium, in the form of surface application or packs, is used only in the event that roentgenotherapy is not available, or in patients who cannot be moved from their homes.

When radiation therapy is to be employed, no definite plan of treatment can be outlined in advance. The marked radiosensitivity of leukemic tissue and the lability of the blood count necessitate extreme caution. In general marked reactions should be avoided, and rapid regressions of leukemic deposits should not be sought. In our series of cases, fractional treatments of roentgenotherapy have been employed, i. e. high voltage therapy (from 180 to 200 kilovolts, 4 milliamperes 0.5 mm of copper plus 1 mm of aluminum filter and the application of from 150 to 250 roentgens at each sitting). Under these conditions radiation is tolerated better and fewer toxic reactions occur. This conforms with recent observations by McAlpin, Golden and Edsall.¹⁷

In our series the areas treated were the spleen in the myeloid cases and palpable lymph nodes and spleen in the lymphoid cases. Occasionally the long bones or the flat bones were irradiated but the response appeared to be somewhat slower. Duke¹⁸ recommends treatment directed to the chest, and Dale¹⁹ advises treatment of the entire body. Recently Craver and MacComb²⁰ published their results with total radiation over a protracted period (from ten days to two weeks) with apparently good effects. This plan is apparently useful in certain refractory cases of chronic lymphatic leukemia.

The effect of roentgen treatment is measured by the degree of symptomatic improvement. In favorable cases there is a rise in the hemoglobin and an increase in the red blood cells, a response that occurs more rapidly in myeloid cases. In lymphoid leukemias the improvement is not so marked. After the first series of roentgen treatments the blood picture may return to normal, particularly in chronic forms, and it may remain so for a variable period—from a few weeks to nine months. The symptomatic improvement, however, may be of longer duration. Additional treatment in our cases has proved less successful. In time patients become more resistant to the treatment and as the disease progresses do not tolerate it well. Toxic symptoms are not infrequent and may occur regardless of the area irradiated or of the amount of treatment. In cases of this type some improvement may be obtained by intravenous infusions of dextrose and saline solution or by blood transfusions.

In our experience radiation therapy is justifiable and useful for acute leukemia. It was employed in twenty

cases of our series. The spleen, spine and ribs were irradiated at intervals of three or four days with from 150 to 200 roentgens²¹. Some of these patients were given one or two blood transfusions to improve the anemia, prior to the roentgen treatment. In most of these no harm was done, but no improvement resulted. However, remissions were observed in three cases of acute leukemia. In two, remissions occurred, which lasted from four to nine months, the third was admitted to the hospital in a moribund state and was given solution of potassium arsenite, roentgenotherapy and a blood transfusion. This was followed by a remission. A relapse set in three months later. The treatment was repeated and again there was a remarkable improvement. Up to the time of writing (eleven months) the patient has apparently been in good health and has a normal blood picture. In our opinion, irradiation is useful in both acute and chronic cases.

Repeated blood counts should be done during a course of radiotherapy. During the administration of the first series, the fall of the white blood cells to 30,000 should serve as an indication for diminishing their quantity and frequency. In subsequent series, changes in the hemoglobin and in the number of red blood cells should be carefully noted. The presence of anemia is the signal to hospitalize and transfuse the patient before treatment is resumed. Knott and Watt²² believe that the phagocytic power of the white blood cells is also an important criterion in connection with roentgen therapy. The loss of phagocytic power should serve as an indication for suspension of treatment, it should, however, be resumed on the return of normal phagocytic activity. It is therefore essential that leukemic cases be kept under the control not only of the radiologist but of the clinician and hematologist as well. This will prevent accidents that are associated with over-dosage of radiation.

DURATION OF LIFE

In our series the duration of life in chronic leukemias was apparently somewhat modified by the inclusion of certain cases formerly regarded as acute. This may be attributed to the more extensive use of blood transfusions in treatment. In cases of chronic myeloid leukemia, 35 per cent of the patients apparently succumb in from four to twelve months, 45 per cent live from two to four years, and a few survive from five to eleven years. In the chronic lymphoid leukemias the duration of life is essentially the same. Most of the patients live from one to four years, a few live from five to fourteen years. In the chronic myeloid leukemias of the leukopenic type, most of the patients live for about one year, a few live longer, and one patient survived sixteen years. Although roentgen treatment does not prolong life, the patient's condition may be improved. It is apparent from our study that there is some justification in the belief that life in some of the acute forms of the disease may be prolonged perhaps to one year by blood transfusions.

SUMMARY

1 The relative occurrence of the three principal groups of leukemia apparently corresponds with the relative percentage of the various types of leukocytes in the circulating blood, namely, granulocytes, lymphocytes and monocytes.

2 The underlying systemic disorders present in all cases is essentially the same. An arbitrary division may be made according to the duration of the disease, acute or chronic, and also according to the number of white blood cells, into leukopenic and leukocythemic forms.

3 Symptomatology, although of great value in differentiating the disease, is unreliable for purposes of diagnosis. This should be based on the characteristic blood changes, which do not depend so much on the number of white blood cells as on the presence and persistence of specific types of cells, such as myelocytes, myeloblasts and relative and absolute lymphocytosis.

4 Confirmatory diagnosis of the more obscure varieties may be made by biopsy on the sternal bone marrow or on a lymph node.

5 The treatment of leukemia is largely symptomatic. Arsenic, transfusions and particularly roentgen irradiations are the chief means of inducing symptomatic improvement, remission or possibly prolongation of life.

CLASSIFICATION AND DIFFERENTIAL DIAGNOSIS OF THE ANEMIAS

RUSSELL L. HADEN, MD

CLEVELAND

An anemia is a decrease in the hemoglobin of the blood below the limit of normal. Since hemoglobin is contained only in the red blood cell, an anemia must result from quantitative or qualitative changes in the erythrocytes. The erythrocyte count may be low or the amount of hemoglobin per cell may be decreased. Red blood cells are always being formed and destroyed rapidly, so that the entire mass of cells is replaced every two to six weeks. An anemia results from a disturbance in the normal balance between destruction and regeneration of erythrocytes and hemoglobin. The red blood cells are formed primarily from the endothelial cells lining the capillary spaces in the bone marrow, especially of the flat bones. Successive stages in the growth of an erythrocyte from the endothelial cell include the megaloblast, erythroblast, normoblast, reticulocyte and mature erythrocyte. Red blood cells in the circulation do not all go through such developmental phases, since multiplication may take place at any immature level, although this is limited largely to the megaloblast and normoblast stages, points designated as critical in erythrocyte development by Sabin¹.

The normal growth of red blood cells requires the elements such as protein, carbohydrate, mineral salts and vitamins, which are necessary for all cell growth. In addition to these nonspecific building stones, certain specific principles must be supplied. Two specific substances are known to be essential for normal erythrocyte development. These are (1) the specific antianemic principle of liver in the absence of which maturation from the megaloblastic stage is abnormal, and (2) iron, which is necessary for normal multiplication at the normoblastic stage and the normal filling of red cells with hemoglobin. Further study may reveal other factors essential to erythrocyte development, but so far

these two are the only ones that have been proved. A deficiency in these specific elements leads at first to a qualitative defect and in time to a quantitative defect in blood formation with a resulting anemia. The growth of erythrocytes may be depressed apart from a lack of cell building material or a deficiency in specific elements by such general factors as lowered metabolism, malnutrition, exhaustion, toxemia, infection, malignancy and poisons or mechanical measures that inhibit normal cell growth in the marrow, such as infiltration of marrow by tumor or leukemia. The defect in blood formation when the function of the marrow is depressed is quantitative, although it is possible that there may be a qualitative factor also, since a poison, such as lead, may interfere with the utilization of one or both of the specific principles necessary for blood formation.

On the other hand, blood is constantly being destroyed at a rapid rate. The red cells fragment as they grow old, are picked up by the reticulo-endothelial cells, especially in the spleen, and are dissolved, the hemoglobin is set free, iron is split off and bile pigment is formed. Iron so released is utilized again and again. The life history of the red blood cell is illustrated diagrammatically in table 1.

The amount of bile pigment formed is the best measure of the rapidity and of the amount of erythrocyte destruction, since this is the normal end product of hemoglobin metabolism. Cells may also be lost mechanically by hemorrhage. A mechanical loss should be evident from the history or examination of the patient, or by tests for occult blood in the feces or stomach contents. With excessive hemolysis, clinical jaundice usually develops because bile pigments are being formed more rapidly than the liver can excrete them. In determining excessive loss of blood, the icterus index of

globin. There are other ways, however, to detect a qualitative change in the marrow, and especially to obtain evidence of a deficiency in the specific substances necessary for normal erythrocyte growth. These tests will be discussed later.

TABLE 2—Phase of Erythrocyte Metabolism

I Increased Blood Loss
(a) Mechanical loss from acute hemorrhage as in
1 Trauma
2 Peptic ulcer
3 Uterine bleeding
4 Disturbance in blood coagulation
(b) Accelerated destruction as in
1 Chronic hemolytic icterus
2 Hemolytic anemia due to infections and poisons
II Decreased Blood Formation
(a) Depression of marrow function in
1 Idiopathic aplastic anemia
2 Cachexia, chronic intoxication, metabolic disturbances, poisons, radioactive substances, malignancy or infiltration of marrow by tumor or leukemia
(b) Deficiency in specific substances necessary for normal red cell formation as
1 Deficiency in specific antianemic factor of liver leading to pernicious and other macrocytic anemias
2 Deficiency in iron and perhaps other unknown substances necessary for hemoglobin formation—chronic hemorrhage, dietary deficiency of iron and disturbance in utilization (idiopathic hypochromic and microcytic anemia)

An etiologic classification of the anemias from a clinical point of view may be made, as in table 2, depending on the phase of erythrocyte metabolism that is involved.

Laboratory aid is necessary, however, even for a clinical classification, and at the same time it provides data for hematologic classification of the anemia. The following laboratory information is required. The technic of the determinations may be found elsewhere.²

- 1 The red cell count
- 2 Hematocrit reading
- 3 Hemoglobin content
- 4 The volume index (relative mean volume of the red cell)
- 5 The color index (relative mean hemoglobin content of the red cell)
- 6 The bile content of the blood plasma (icterus index)
- 7 The reticulocyte count.
- 8 The diameter of the red cells, qualitative changes in the stained cells, the number and type of leukocytes, the platelet count, and the coagulation and bleeding time, which may be of help in some cases.

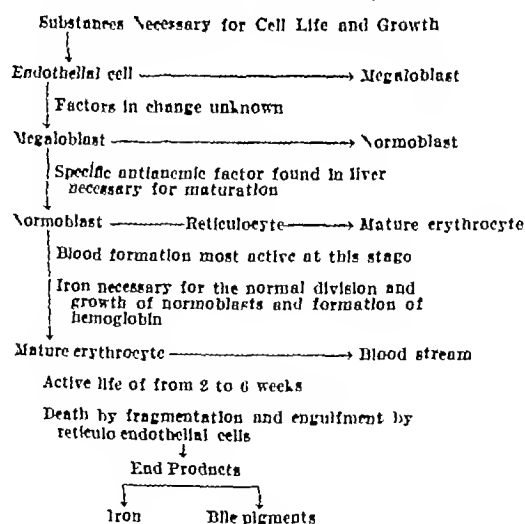

On the basis of the size and hemoglobin content of the red cell as determined in such an examination, the anemias are classified from a hematologic standpoint as follows:

- 1 Normocytic and normochromic volume index normal, color index normal
- 2 Normocytic and hypochromic volume index normal, color index low
- 3 Macrocytic and hyperchromic volume index increased, color index increased
- 4 Macrocytic and normochromic volume index increased, color index normal
- 5 Macrocytic and hypochromic volume index increased, color index low
- 6 Microcytic and hypochromic volume index low, color index low

I have illustrated in figure 1 the mean size of the erythrocyte and its mean hemoglobin content in the six different types of anemia.

² Haden R. L. The Technic of a Blood Examination. J. Lab. & Clin. Med. 17: 843-859 (June) 1932.

TABLE 1—Life History of the Erythrocyte

the blood plasma is measured and thorough search for evidence of hemorrhage is made by means of the history and laboratory tests.

The most accurate indicator of the activity of erythrocyte regeneration in the marrow is the level of reticulocytes in the circulating blood, since these are young cells. The number of reticulocytes is the only measure of a quantitative increase in marrow activity other than the routine estimations of red cells and hemo-

The blood changes and the clinical classification may be correlated. In the anemias caused by acute hemorrhage the number of cells and the quantity of hemoglobin are equally reduced which indicates a reduction in the number of cells with those remaining normal in size and hemoglobin content. The anemia is normocytic and normochromic. In chronic hemorrhage or if the acute hemorrhage is sufficient to produce an iron deficiency, the picture is that of an iron deficiency anemia with a low volume index and color index. The icterus index is normal or reduced and the reticulocyte count is increased with normal marrow response.

In the presence of accelerated destruction of erythrocytes, the most characteristic clinical feature is the increased icterus index. If the process is chronic, the marrow is normally overactive, so there is often a great increase in reticulocytes with red marrow in the long bones. Since reticulocytes tend to be slightly larger than normal mature red cells, some increase in the size (volume index) and color may be found, although this is variable.

In all types of anemia resulting from decreased formation of erythrocytes the reticulocyte count is low. In true idiopathic aplastic anemia and simple depression of marrow activity the effect on the bone marrow is usually purely quantitative so fewer cells are produced by the marrow but those that are formed are normal. The color, volume and icterus indexes are within normal limits. Often the effect of lowered metabolism, malignancy, poisons and toxemias is to interfere with the formation, absorption or utilization of one or more of the specific principles necessary for normal blood

formation. In such cases the blood takes on the characteristics of a specific deficiency anemia although the actual cause is malignancy or some other abnormality.

In the specific deficiency anemias the changes in the blood are characteristic. If the anemia is due to a deficiency in the specific antianemic factor of liver the bone marrow is crowded with large cells which are unable to mature and these die in situ in excessive numbers. The icterus index is high for this reason. The reticulocyte count is low

conditions is thus a macrocytic and hyperchromic anemia with high icterus index and low reticulocyte count.

With an iron deficiency there is first a decrease in hemoglobin, each cell carries less hemoglobin, so the color index is low since the total count normally remains high. Less hemoglobin is destroyed, so the icterus

Fig. 2—Typical laboratory observations in the various clinical groups of anemia.

index is lower than normal. Often the plasma is very clear. Almost the sole function of the red cell is to transport oxygen. With a prolonged iron deficiency and a great decrease in hemoglobin there is no need for cells of normal size, as the number may not change greatly. In such a deficiency, in time the mean size of the cell becomes smaller, although the hematocrit reading seldom becomes less than two thirds of normal. The characteristic anemia of an early or mild iron deficiency is a normocytic and hypochromic anemia with the icterus index 1 or less, and with little change in the reticulocytes, in a severe or chronic iron deficiency the characteristic anemia is microcytic and hypochromic, with a marked decrease in the icterus index.

The characteristic blood changes in the different clinical groups of anemia are shown in figure 2.

Not infrequently more than one factor is operative in the causation of an anemia, so the blood changes represent a summation of these characteristics for the different types of anemia. If there is a deficiency in both iron and the antianemic factor of liver, the microcytosis and the hypochromia characteristic of the iron deficiency may be neutralized by the macrocytosis and hyperchromia brought about by the deficiency in the antianemic factor of liver. The cell size and hemoglobin content may then be within normal limits. Malignant disease may depress the marrow, interfere with the utilization of a specific factor, and also cause hemorrhage. In such an instance there are three factors in the causation of the anemia. A careful study usually reveals all the factors.

Fig. 1—Diagram to illustrate the six groups of anemia on the basis of volume and hemoglobin content of the red cell.

because few cells get into the blood stream. Such cells as do get out are large and contain more hemoglobin than normally. Hence the volume and color indexes are high, as well as the icterus index while the reticulocyte count is low. The disturbance in the marrow is at the megaloblast stage of red cell development. The characteristic anemia in pernicious anemia or related

COMMENT

If the blood is studied correctly and adequately, if a careful history is obtained and if the patient is examined completely, a case of anemia can almost always be correctly classified, both clinically and hematologically.

It is apparent that a correct diagnosis is of necessity prerequisite to the proper and adequate treatment of any patient with anemia. The factors in the production of anemia are relatively few, but frequently more than one factor may be operative. Thus with adequate specific treatment of pernicious anemia or iron deficiency not infrequently develops if the response to therapy is rapid. Likewise there may be a quantitative depression of bone marrow activity and also a qualitative deficiency caused by interference with the absorption or utilization of the specific principles necessary for the normal development of the erythrocyte. Infection is often a factor in the specific deficiency anemias. Thus, if an infection develops in a patient under treatment for pernicious anemia the dose of the antianemic factor of liver must be increased, showing that the infection interferes with the absorption or utilization of the specific principle.

In every case an abstract laboratory diagnosis from a hematologic standpoint must be made as well as a

anemias or in the macrocytic anemias when the color index is much lower than the volume index (low saturation index). Liver is an excellent food to supply nonspecific factors and hence may be tried in every type of anemia, although it probably has a specific effect only in macrocytic anemia.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. KRACKE AND HORTENSE GRAVER, DRS. ROSENTHAL AND HARRIS AND DR. HADEN

DR. CHARLES A. DOAN, Columbus, Ohio. In the Research Service at Ohio State University, seventy-five cases of leukemia have been studied during the last four years. Using the supravital criteria in addition to the usual methods for morphologic identification we have made differential diagnostic studies of the types of cells involved in each case. The relative incidence of monocytic leukemia, in our series about 15 per cent, is surprising in view of the relative infrequency with which this type of leukemic dyscrasia has been reported in the past, 45 per cent were lymphatic and 40 per cent myeloid leukemia. Four post-mortem studies in the group of eleven cases diagnosed as monocytic leukemia confirmed beyond question the underlying pathologic reticulum cell hyperplasia characteristic of this type. Some light has been thrown on the question of 'mixed leukemia' in this study. In our experience to date, a 'mixed leukemia' has been always a monocytic leukemia. The problem of aleukemic leukemia is being confused with agranulocytic angina. More than 80 per cent of the patients referred to us with a low white count—presumably specific granulopenic states—have not conformed to the Schultz syndrome and many have shown the blood picture and pathologic changes of acute leukemia. We have found prognosis based on either physical or laboratory examination to be extremely hazardous in leukemic patients. A patient with less than 1500 total white count and the majority of the cells myeloblasts lived for eight months without symptoms other than some weakness and an occasional lingual ulceration. Another patient was sent home with 400,000 total white count, 90 per cent of the cells being myeloblasts, and with a beginning gangrene of the face, and returned five months later in remission with 11,000 white cells but with the same qualitative differential. The making of a diagnosis of leukemia especially in elderly individuals with an elevation of the white count, the lymphocytes predominating, is not always easy. Therapy must be individualized. In the acute cases with "blast" cells predominating, x-rays and radium are usually contraindicated. In the more chronic cases of all three types of leukemia small graduated doses of x-rays (starting with 100 roentgens) may be advantageously alternated with solution of potassium arsenite in successive courses of treatment. The development of a refractory tolerance may thus be overcome. We have been able to maintain both chronic and subacute manifestations of the disease in control for periods as long as from four to five years, and the patients in fairly good health, on such a regimen. The treatment available at the present time is, of course, only palliative and only temporarily if at all effective.

DR. VICTOR LEVINE, Chicago. Dr. Kracke has come to the conclusion that monocytic leukemia is a phase of myelogenous leukemia. This is in accordance with the view of Naegeli. Downey, however, has divided monocytic leukemia into two types: the Schilling type and the Naegeli type. By the Schilling type he means the true monocytic leukemia, with a preponderance of monocytic cells in the bone marrow and blood stream. By the Naegeli type is meant the monocytic phase of a myelogenous leukemia, a condition which I have observed at the Cook County Hospital and in which the myeloid cells predominate in the bone marrow despite the fact that the peripheral blood shows a majority of monocytic cells. To the types of acute leukemia mentioned there might be added two other types, megakaryocyte leukemia (which is quite rare) and stem cell leukemia. Many hematologists will not speak of a stem cell leukemia but there are a certain number of acute leukemias in which the predominant cell is so immature that it is impossible

Fig. 3—Embryologic cycle of the red cell of man (after Sabin) and the point of action of the specific principles necessary for normal red cell formation.

clinical classification based on the method of production of the anemia. All possible factors must be evaluated in planning treatment. To accomplish this the life history of the red cell must be kept adequately in mind, and the results of a complete blood examination must be known. The results of treatment are also determined by a careful blood study. In pernicious anemia the macrocytosis of the erythrocytes disappears with complete treatment, in an iron deficiency anemia, if enough iron is given, the cells become larger and are filled with hemoglobin. I have illustrated in figure 3 the close relation of treatment to the embryologic cycle. Each of the two specific methods of treatment of anemia (iron and liver and liver substitutes) bears a definite relation to a stage in the life history of the red cell. Thus the antianemic principle of liver acts at the megaloblast stage, while iron acts at the normoblast stage. Liver substitutes help only the macrocytic anemias, while iron is indicated only in the hypochromic

to classify it as a myeloblast, monoblast or lymphoblast and it is accordingly called a stem cell. Rather than try to describe this type of cell, I will refer to an article by Dr. Forkner in the January 1934 issue of the *Archives of Internal Medicine*. He has one plate of excellent colored illustrations on which are the cells of a case diagnosed acute lymphatic leukemia. Forkner calls these white cells lymphocytes, but from their appearance they are certainly stem cells.

DR. W. EDWARD CHAMBERLAIN, Philadelphia. The radiologist must make a thorough study of his own cases of leukemia, in addition to studying the literature and attending such symposiums as this. In studying his own cases, I would urge him to make a practice of drawing up charts of blood counts based on absolute numbers of various cell types instead of percentage figures. For example, let us suppose that on a certain date the total white blood count is 100,000 and that 3 per cent of the cells are lymphocytes. Let us further suppose that ten days later the total white blood count is 30,000 and the lymphocyte count is 10 per cent. Actually the lymphocyte differential has increased from 3 per cent to 10 per cent, when expressed in percentages, while the absolute number of lymphocytes has remained exactly the same, namely, 3,000 cells. One should be primarily interested in the increase or decrease in total, and in the absolute numbers of various cell types. Charts or tables based on percentages do not give the lucid picture that can be obtained from charts or tables based on the absolute numbers of cell types.

DR. GEORGE J. KASTLIN, Pittsburgh. Within the last three months I have had under observation three cases of aleukemic leukemia of different types. One was a case that was first interpreted as an aplastic anemia, which continued for nine months. Approximately twenty-eight or thirty transfusions were given by one of my colleagues. This was a case that could not be definitely classified clinically as leukemia but at autopsy was definitely of an aleukemic type. The second case was also one in which confusion arose in diagnosis between aplastic anemia and leukemia. There was profuse hemorrhage from the nose and mouth, with a low platelet count but with no distortion in the bleeding or coagulation time. Although there were no abnormal lymphocytes in the blood stream, it appeared clinically as an aleukemic leukemia and was proved so at autopsy. The question came up whether roentgen treatment could be administered in the doses that are advocated by some in granulocytopenia or in other leukemias. The third type was a conventional type of leukemia with low white count but with a typical myelogenous blood picture. I present these three types, seeking information with regard to the possibility of roentgen therapy in addition to transfusion, the use of arsenic and supportive measures in general.

DR. NATHAN ROSENTHAL, New York. Dr. Doan's studies of living cells are important. Observations of the activity of cells after roentgen treatment may prove to be an important guide for continuation of roentgen treatment. Dr. Kastlin's cases of marked leukopenia with definite leukemic changes at the postmortem are interesting. In such cases the biopsy on the sternal bone marrow during life is an important aid in diagnosis. Roentgen treatment is contraindicated in such leukopenic states. It is not followed by good results and may lead to production of a greater leukemia and secondary septic complications.

Laboratory Doodads—In the Epidemion, there are a considerable number of case histories, quite as thoroughly recorded, from day to day, as many of our modern ones, upon which diagnostic judgment can be based. In many instances, the observations of Hippocrates are so precise that we can often supply, from modern knowledge the exact type of infection—not infrequently the micro-organism that must have been responsible for the individual conditions. In regard to many nonsurgical conditions Hippocrates did quite as well, we surmise as will be possible for the modern general practitioner or "family medical adviser" who is so dear to the hearts of many of our reactionary contemporaries, and who, by a turn to medical muzzle loading is to emancipate our profession from all the newfangled laboratory doodads—Zinsser, Hans Rats, Lice and History. Boston, Little, Brown & Co., 1935.

THE GASTRO-INTESTINAL MANIFESTATIONS OF UROLOGIC DISEASE

SIDNEY A. PORTIS, MD

AND

J. S. GROVE, MD

CHICAGO

The gastro-enterologist is frequently confronted with symptoms, referable to the abdomen, that cannot be explained on the basis of pathologic changes in the gastro-intestinal tract. In a number of cases, exhaustive study and resultant symptomatic management failed to relieve the symptoms. We therefore sought a possible explanation in the urinary tract, in spite of the fact that the urinary symptoms were either lacking or entirely in the background.

Metabolic disturbances associated with the nephritides frequently give rise to symptoms that are purely gastro-intestinal, but these are associated with corresponding blood changes with absorption of the toxic products. This group of cases is not considered in this presentation because the cases are so obviously renal in origin.

With these facts in mind we began to search for a possible explanation of this curious relationship. Reviewing the neurologic aspect, we note the interrelation of the nerve supply of the upper urinary tract, and the organs of digestion. Smith¹ has carefully shown this connection. He maintains that since both are supplied by the vagus and sympathetic nerves, any disturbance of the kidney may be reflected through the gastro-intestinal tract. The connecting link is through the celiac ganglion. Therefore it is reasonable to suppose that impulses originating abnormally in the urinary tract may produce gastro-intestinal symptoms without pathologic changes.

Numerous authors have also emphasized the close anatomic approximation of the kidneys with other abdominal viscera. This is especially true of the right kidney in relation to the gallbladder, duodenum, pancreas and ascending colon. However, in this group of cases the kidneys play the predominant role.

There are no pathognomonic signs or symptoms that would lead to a more accurate diagnosis. This is more a matter of exclusion, the possibility of such an interrelationship being kept in mind.

Frequently a careful history will reveal a urinary disturbance, particularly in women. They complain, in addition to their other symptoms, of a frequency and desire for urination, and a feeling of incompletely emptying the bladder. There may also be an urge which must be satisfied within a relatively short time. Difficulty in starting the stream is not uncommon. Smarting or burning may be present. In the male, similar but more pronounced urologic changes may cause the distress. From the gastro-intestinal standpoint the symptoms frequently simulate gallbladder disease, occasionally ulcer—especially duodenal—and many are treated for so-called colitis for a period of years, and in some, even operative intervention has been resorted to, with the extirpation of organs that show little or no change, with a persistence of complaints after surgery.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

¹ Smith E. C. Canad. M. A. J. 28: 281-283 (March) 1933.

We wish to emphasize a rather large group of cases, particularly in women, that has often escaped the attention of the internist in which definite pathologic changes have been found in the urethra. Until of late, very little reference has been given in the literature to this group. In spite of these reports, the mention of urethral pathologic changes in females, particularly strictures, elicits a feeling that this condition is a rare one. This, however, is not true, for if the urethra would be examined by gynecologists and general practitioners as a routine during pelvic examinations, this entity would be found rather frequently.

Urologically, the changes are those of a definite stricture, usually in the anterior third of the urethra. Here one finds a definite narrowing and catheterization is done with difficulty if at all. Passage of a bougie reveals a definite "hang." The back pressure in these bladders results in the cystoscopic changes closely resembling those seen in prostatic hypertrophy—the degree depending on the duration of the stricture and the severity of the obstruction. Also, in the female, contractures may occur at the bladder neck, as well as diffuse polypoid formation.

We especially disregard at this time that group of cases known as ureteral strictures, recognizing that they may be a factor, but the increasing evidence points to the fact that they are not so common as previously mentioned by Hunner. That they occur there is no doubt, but are they as common as so often diagnosed?

In this connection we are reporting a group of thirty cases. For the sake of brevity we will review a few outstanding clinical pictures to emphasize this phase. In the cases herein cited the usual work up was given of a complete history and physical examination, complete blood count and differential, urine, stool, Wassermann and Kahn tests, basal metabolic rate, complete blood chemistry when indicated, and complete gastro-intestinal roentgen examination with or without a cholecystogram. In some cases a barium sulphate enema was given. Deviations from normal of these laboratory data will be cited if they have any significance, and, when omitted, it is assumed that they are within the limits of normal.

REPORT OF CASES

CASE 1—Miss E. S. consulted us, March 1, 1928, for pain in the upper part of the abdomen. During the last twelve years she had had attacks of diffuse abdominal pain, coming on in the nature of attacks. Pain was rather severe and frequently radiated to the back on the right side. Attacks usually lasted from twenty-four to forty-eight hours and were accompanied by a temperature of 102 F. There had been no nausea or vomiting. A great deal of belching occurred, however. Six months before she had an attack of pain, accompanied by jaundice, which lasted ten days. She had previously been told that she had blood and pus in the urine. Cystoscopy was done at that time and a kidney infection was diagnosed. She was seen subsequently by another urologist, who confirmed this opinion, and during the last two years an appendectomy and cholecystectomy had been performed, following the latter operation there was slight improvement and then again a return of the symptoms. Analysis of the urine was negative on several examinations. Under suitable management no improvement was noted, urologic examination was done, and at this time a marked fibrous stricture in the last two thirds of the urethra was noted. A clear urine and normal bladder tolerance was observed. There were numerous areas of trabeculization over the wall of the bladder. On the floor of the bladder, and chiefly in the region of the right ureteral orifice, there was a marked bullous edema. The right ureteral orifice was embedded in this edema. The left orifice was essentially normal. Both ureters were catheterized unobstructed and a clear urine was

obtained from each side. A renal function indigocarmine test revealed a return in three minutes on the right and three and one-half minutes on the left side, in good concentration. She did not report again for another year and a half, at which time a recheck of the lower part of the urinary tract was done with similar observations. Subsequent dilations of the urethral stricture in this particular patient relieved her symptoms, and she has been well since.

CASE 2—Mrs. E. J. S., aged 47, who consulted us, Aug. 2, 1927, gave a history of cholecystectomy and appendectomy nine months before. However, there was still a persistence of belching and a bitter taste in the mouth. Symptoms were only slightly and temporarily relieved by the operative intervention, and although she had been fairly comfortable for six months there was a definite return of her symptoms. A complete examination at this time revealed no pathologic changes to explain the recurrence of symptoms, and in this particular case there was no nocturia and frequency of urination. However, during the course of observation of a few months, a frequency did develop, and cystoscopic examination at that time revealed a firm fibrous stricture, 2.5 cm. from the outlet, with marked trabeculization of the bladder. Both ureteral orifices were normal, and there was moderate trigonal cystitis. Subsequent dilation of the urethra in this particular case completely relieved the gastro-intestinal symptoms, and the patient has been free from symptoms for the last five years.

Most internists are acquainted with the symptoms of nephroptosis and their attending phenomena. However, there is a certain group of cases in which the gastro-intestinal symptoms play the predominant rôle. In this connection we are reporting the following case.

CASE 3—Mrs. R. F., aged 27, who consulted us, Aug. 29, 1923, complained of pain in the right side, nausea, lumbar pain, headache, loss of weight, and a tendency to perspire easily. For the past five years she had had pain in the right side which was more or less constant. Appendectomy four years previously for this complaint failed to relieve her symptoms. The pain radiated up into the back and to the scapula. She felt nauseated when the pain was at its height, it never was referred to the pubic region and she never required opiates for relief. There had been some fullness and distention after meals. Noteworthy physical changes were a systolic murmur at the base of the heart, with a blood pressure of 142 systolic and 90 diastolic. There was some tenderness over the gall-bladder region, and a mobile right kidney was observed. Subsequent gastro-intestinal roentgenograms revealed a prepyloric spasm on the lesser curvature side of the stomach which was distinctly tender. Otherwise the gastro-intestinal examination was negative. She was treated for a period of three years off and on, on gastro-intestinal management, with improvement and relapses. In 1926, with the return of symptoms, a cholecystogram was made, and what was thought at that time to be a pathologic gallbladder was observed. On suitable management there was a return of her previous phenomena and at this time it was thought wise to investigate the urinary tract. April 17, 1928, Dr. Kretschmer reported the following: Cystoscopic examination was negative, except for a freely movable right kidney, and a pyelogram showed the right kidney pelvis in normal position, with the patient lying flat on the table, and a prolapse of the pelvis down to the crest of the ilium when the patient stood up. The kidney could easily be displaced so that the pelvis was seen over the spine. After much discussion, and with some reluctance on the part of the urologist, it was finally decided to do a right nephropexy. This was subsequently done, and for the last six years the patient has been completely relieved of all of her symptoms and has had no recurrence of the gastro-intestinal manifestations.

Following this line of thought as to displacement, it is interesting to report the following case, illustrating pressure phenomena.

CASE 4—Miss S. G., aged 43, who consulted us, Feb. 7, 1928, complained of pressure in the epigastrium and substernum. For the past three or four years the patient had had recurrent

pains in the epigastric and substernal regions, coming on during the day or night, never awakening her, and lasting for an hour or so. There was no particular relation to meals and no nausea, vomiting or jaundice. There was, however, excessive belching and passage of gas. Physical examination revealed frozen, irregular pupils, a definite systolic murmur in the aortic region, and a blood pressure of 168 systolic and 114 diastolic. There was definite fulness in the epigastrium, and there was a dull area displacing the normal stomach tympany. Examination of the rectum and vagina did not show any pelvic tumor mass. Repeated examinations of the urine showed no noteworthy changes, and the same was true of examination of the stool. The stomach acids were ten free and twenty total on the Ewald meal. The motor meal showed no evidence of retention. The Wassermann reaction and a previous spinal fluid examination were negative. The renal functional test gave a return of 35 per cent the first hour and 40 per cent at the end of the second hour. The blood sugar was 90 mg and nonprotein nitrogen was 31 mg. Fluoroscopic examination of the chest and abdomen revealed no noteworthy changes of the chest, however, the cardiac end and the greater curvature side of the stomach were displaced to the right half of the abdomen. The duodenal bulb, when brought into view, was normal. Beneath the left side of the diaphragm there was a region similar in density to that seen on the right, occupied by the liver. Plates confirmed the fluoroscopic observation showing a displaced stomach to the right and a depressed transverse colon into the pelvis. Cystoscopic examination revealed no noteworthy bladder changes. Indigocarmine injected intravenously appeared on the right side in two and one-half minutes in good concentration and on the left side in four minutes in fair concentration, and one-half minute later in excellent concentration. The left pyelogram showed a nephroptosis of the third degree. There was a slight degree of hydronephrosis. There was a tortuosity of the ureter, due to ptosis of the left kidney. There was no evidence of ureteral stricture and the pelvis and calices were practically normal. It was thought that the ptosis of this kidney was due to extrarenal pressure. Subsequent laparotomy by Dr. H. M. Richter revealed a large solitary cyst of the upper pole of the left kidney. This was subsequently resected and the kidney left in situ. Following the removal of this cyst, the patient's gastro-intestinal symptoms completely subsided.

CASE 5—Miss M. S., aged 29, who consulted us July 15, 1926, complained of distress after eating and vomiting. She had had an appendectomy sixteen years before. For the last five years she had had attacks of indigestion. These would come approximately every month and last for about two weeks, they were particularly distressing after the patient ate fat and greasy foods. Physical examination other than tenderness over the gallbladder and epigastric regions, was essentially negative. Gastro-intestinal and gallbladder examinations revealed what appeared to be a pathologic gallbladder with stones. She was advised to have a cholecystectomy, and a single stone was found in the gallbladder. Following this a thyrotoxicosis developed and a subtotal thyroidectomy was done, and following the thyroidectomy the patient was fairly comfortable.

There was again a return of the previous gastro-intestinal manifestations, however with some urinary distress. Vaginal examination revealed several large fibroids of the uterus. A cystoscopic examination revealed, particularly on the left side, an invaginated area of the bladder wall. This was about 5 cm in diameter. There was distinct hyperemia of this area. The trigon and ureteral orifices were normal. Cystograms showed a deformity of the left lateral wall of the bladder conforming to the cystoscopic picture. Following the removal of the fibroid uterus, the patient's urinary symptoms entirely disappeared, and she has been free from gastro-intestinal manifestations for the last two years.

Still more interesting are patients in whom one should readily suspect urologic manifestations that are entirely overshadowed by gastro-intestinal phenomena. In the male urologic disease is frequent, and yet it is easily overlooked as the causative factor for the basis

of the symptoms. This will be exemplified by the following cases.

CASE 6—F. B., a man, aged 41, who consulted us, Nov. 13, 1931, complained of distention of the abdomen, belching and nervousness. For the last several years the patient had experienced a feeling of distention, especially across the upper part of the abdomen, coming on every day, usually noticed in the morning and late in the evening, and even while he was asleep. However, there was no relation to food taking. About a year before he had had a very severe pain under the right costal margin, which lasted for three or four weeks, not enough to incapacitate him and not associated with any vomiting or jaundice. There had been no loss of weight, and his past history was essentially negative. Physical examination revealed a markedly accentuated aortic tone, a blood pressure of 160 systolic and 116 diastolic, with definite tenderness over the gallbladder and sigmoid regions. The urine and stool examinations were essentially negative. Roentgenograms revealed numerous apical diseased teeth. The basal metabolic rate was 0 per cent, the blood sugar 88 mg, nonprotein nitrogen 23 mg, and a renal functional test 40 per cent at the end of the first hour and 30 per cent at the end of the second hour. Roentgen examination of the gastro-intestinal tract revealed no noteworthy changes of the stomach or duodenum. A cholecystogram revealed a gallbladder within the limits of normal. Because of the hypertension it was thought that conservative gastro-intestinal management would be the procedure of choice. On what was presumed to be adequate gastro-intestinal therapy, however, his symptoms did not markedly decrease. A diurnal and nocturnal frequency then developed, associated with some slight difficulty on starting the stream. Rectal examination revealed a small, firm, irregular and nontender prostate. Both seminal vesicles were slightly enlarged. Prostatovesicular smear revealed from 20 to 30 pus cells per high power field. When an attempt was made to sound the urethra, a definite firm, linear stricture was encountered in the membranous portion of the urethra. Dilatation of this stricture with adequate prostatic massage completely relieved the gastro-intestinal manifestations and the patient has been comfortable since.

CASE 7—C. A. E., a man, aged 41, consulted us, Feb. 28, 1927, for vague abdominal symptoms, associated with loss of weight, with no genito-urinary history. It was thought that he had a low grade disease of the gallbladder, and under subsequent management he seemed somewhat improved. However, some three or four years later pain developed in the left side, with a return of the abdominal manifestations, and he also noticed a frequency of urination. Because we felt that there might be a urologic condition in the background, this investigation was done instead of a gastro-intestinal examination. The external genitalia were essentially normal. Rectal examination revealed a smooth nontender, bilaterally enlarged prostate. Cystoscopic examination revealed on the left lateral wall, just above the left ureteral orifice, an opening of a large diverticulum. This was about 1 cm in diameter. Scattered throughout the bladder were numerous coarse trabeculae. The interureteral ridge was markedly hypertrophied. Examination of the bladder neck showed a definite hypertrophied median lobe. The lateral lobes did not show any marked changes. A subsequent intravenous pyelogram demonstrated that the left ureter took a tortuous course above the bladder and was pushed to the midline by the diverticulum. There was no evidence of hydronephrosis, and the removal of this diverticulum and a prostatic resection of the median lobe were advised. The urologist in his home town, however, felt that the diverticulum was all that should be removed and there was some slight improvement following this operation. With the return of symptoms the urologist was convinced that a resection of the prostate was indicated. After this was performed, the symptoms entirely disappeared and the patient has been free from gastro-intestinal manifestations.

CASE 8—S. L., a man, aged 47, who consulted us, Aug. 19, 1929, complained of abdominal distress, belching and distention. For the past two or more years the patient had had regular recurrent periods of abdominal distress, coming on about an hour after meals, especially after fried and greasy foods, associated with fulness and distention, and excessive belching. The

past history, other than a herniotomy fourteen years before and an appendectomy eleven years before, was essentially negative. Physical examination revealed no noteworthy manifestations. Examination of the urine and stool was negative. There were no noteworthy changes in the gastric content. Roentgen examination of the gastro-intestinal tract revealed a normal stomach and duodenum. A cholecystogram showed what appeared to be a pathologic gallbladder. Subsequent gastro-intestinal management made only little improvement in the patient. During the course of this observation symptoms of frequent and nocturnal distress developed and cystoscopic examination was thought advisable. At this time it revealed a residual bladder urine of 3 ounces (90 cc.) and normal bladder tolerance. A slight, coarse trabeculation on the posterior wall of the bladder, normal ureteral orifices, and a depressed trigon with median lobe enlargement which was definitely elevated and hypertrophied, with the lateral lobes within the limits of normal, were found. Following an adequate median lobe transurethral resection, the gastro-intestinal manifestations completely disappeared.

CASE 9—S. L., a man, aged 24, complained of abdominal distress coming on some two hours after eating. This was associated with frequent nausea and vomiting. Gastro-intestinal examination was essentially negative. He was treated with ulcer management, with no improvement of symptoms. He had one severe attack of epigastric distress resembling that seen in a penetrating duodenal ulcer and when seen by his internist surgical intervention was suggested for a penetrating and probably perforated duodenal ulcer. However after the clinical picture was reviewed with the urologic manifestations it was deemed advisable to investigate the urinary tract with the result that a definitely enlarged and tender left seminal vesicle was found which on massage showed a large number of pus cells. After massage of the seminal vesicle there was an immediate abatement of the gastro-intestinal symptoms. During the last four years, while under observation there has been a recurrence of the gastro-intestinal symptoms which have not mended under medical management and it is exceedingly noteworthy to find that with a repetition of urologic therapy there has been a complete remission of the symptoms.

COMMENT

It is evident from these various cases that urologic disease can and does cause gastro-intestinal symptoms. But how frequently is this etiologic factor overlooked? The more recent addition of intravenous pyelography to the armamentarium of diagnostic procedures has shed even greater light on this interesting phase of disease. We recognize the fact that intravenous pyelography has some shortcomings, but this should not detract from its helpfulness in leading to more accurate diagnoses in certain groups of cases.

The cooperation of the urologist with the internist has brought about a clearer understanding of many obscure pictures that heretofore have not been recognized, and, what is more important, that have been treated for many years symptomatically with no relief. Multiple operations are resorted to, and no improvement in the original picture is brought about. These patients are frequently mislabeled—treated as “neuro,” or hypochondriacs—and are classified frequently in that all inclusive diagnosis “colitis,” and yet are no better after the best of talent has had an opportunity to prove its skill.

CONCLUSIONS

With these facts in mind we feel justified in drawing the following conclusions:

- 1 The interrelationship of the nerve paths of the urinary and gastro-intestinal tract may explain this curious relationship of symptoms.

- 2 Women with urethral pathologic changes frequently show gastro-intestinal manifestations.

- 3 Pressure phenomena and displacement play a role in a certain group of cases.

- 4 Pathologic changes in the lower part of the urinary tract in the male may cause symptoms, particularly in middle aged men.

- 5 Finally, we do not offer this evidence as a panacea for all obscure gastro-intestinal complaints. However, we do feel that it is justifiable for the gastro-enterologist to become urologically minded enough to explain at times these many obscure clinical pictures. More hearty cooperation between the internist and the urologist should produce a more accurate diagnosis in a certain percentage of cases that do not react to recognized medical care.

104 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR HARLOW BROOKS, New York. In my service are many patients who enter the hospital through the gastro-intestinal outpatient department, complaining of nausea and vomiting. These cases may include pretty nearly everything from hysteria to pregnancy. In a considerable number of cases we found that this was the result of urologic conditions and yet they were thrown on the internist and gastro-enterologist for diagnosis. In the first place there is traumatism of the kidney. Nausea and vomiting are the most outstanding signs of renal disease. Pyelitis causes nausea and vomiting with great frequency, and so do stones renal abscess, the large solitary nephritic abscess or, still more frequently, the small cortical abscesses, which are so difficult of diagnosis even in the hands of the expert urologist. Tumors of the colon and stomach are mistaken frequently for tumors of the urinary tract, and vice versa. One should never forget the close anatomic relationship between the colon, the gallbladder and the stomach in their proximity to the kidney or even to the urinary tract lower down. It is easy to assume when one finds a case of apparent tumor of the stomach with the characteristic signs and symptoms of carcinoma that the stomach is the primary focus, but sometimes an inquisitive finger forced into the anus will show that the growth really originated in the prostate. Prostatic carcinoma frequently metastasizes early in the region of the colon or the stomach. Of course, that makes a great deal of difference if one has in mind a subtotal gastrectomy. Gallbladder disease is so frequently mistaken for urinary disturbances that I hardly need to mention that we have found in the past month in the hospital several cases sent in as gallbladder disease but really due to septic nephritis. Renal tumor, pyelitis, cortical abscesses, solitary abscess, cysts of the kidney, quiet stone, proctitis, hemorrhoids and rectal disturbances of almost all sorts may simulate one another closely. Stricture, abscess and ulcerations of the sigmoid and rectum in particular are often secondary to prostatic disorder. So far as their symptomatic picture is concerned prostatic abscess, carcinoma of the prostate and pelvic abscess are quite frequently associated and stricture of the rectum may be due to widespread pelvic abscess possibly originating from an inflamed prostate. Three cases have recently entered the hospital under the diagnosis of typhoid. One who recalls the occasional difficulty of diagnosing this infection in the early stages will not be surprised to find that those three cases were instances of prostatic abscess. Then there is the frequent story of chronic appendicitis mistaken for an incarcerated stone in the ureter. I want to point out that the gastro-enterologist must be an internist with a particular equipment and skill and, as part of the internist's training, he must not forget that he must know a good deal of urology.

DR CHARLES M. McKENNA, Chicago. Many patients have been sent out of the doctor's office after a complete work up on gastro-intestinal disease as neurotic when in reality they were suffering from a pathologic condition of the urogenital tract. When one takes into consideration that the solar, aortic, renal hypogastric ovarian prostatic and vaginal plexuses innervate both the gastro-intestinal tract and the urogenital tract it becomes evident that any lesions of the urogenital tract

may produce symptoms in the gastro-intestinal tract. I would like to point out some conditions that I have observed in the Research Hospital in Chicago. Seminal vesicle disease will illustrate my point. Patients suffering with seminal vesicle disease may exhibit referred pain at McBurney's point. Excretion urography has been a great aid to the internist. Internists are now using more skodan in eliciting gastro-intestinal disease than ever before.

DR JULIUS FRIEDENWALD, Baltimore. Aside from renal disease, I have been especially interested in two urologic conditions giving rise to gastro-intestinal symptoms. The first is the presence of stone in the pelvis of the kidney, which may produce symptoms resembling duodenal ulcer or cholelithiasis, giving rise to pain several hours after meals, with signs of hyperacidity or reflex, and colicky pain in the upper part of the abdomen. The true condition may remain obscure unless a thorough investigation is made. The second is that associated with prostatic obstruction in which the digestion becomes markedly impaired and nausea, vomiting, eructations, abdominal pain, distention and emaciation become so prominent that the presence of carcinoma of the stomach may be suspected. In a number of instances of this type in which the patient had been previously under treatment for a considerable length of time for a supposed gastric cancer, the examination pointed directly to toxemia due to a prostatic hypertrophy. It is therefore of importance to bear in mind that, in individuals past middle life in whom gastro-intestinal symptoms are prominent, the prostate should always be examined.

DR. LEON BLOCH, Chicago. The occurrence of gastro-intestinal symptoms as the chief manifestations of urologic diseases up to recently has been stressed very little. This statement excludes of course conditions of severe colic with reflex nausea and vomiting and the patients in whom the symptoms are toxic manifestations of acute seminal vesiculitis or prostatitis. The symptoms group themselves under four types, gastroduodenal, cholelithiasis, colic and appendiceal. The following is an example of the gastroduodenal type. Z. L. complained of regularly recurring distress after meals. A duodenal defect was found on fluoroscopy. He improved very little on medical treatment. Subsequently a urethral discharge appeared, which was treated for six months without avail. At this time a roentgenogram revealed a renal calculus. All the symptoms disappeared after removal of the stone. Recently a young doctor with a similar gastric history, a duodenal defect and a negative urinalysis and who did not respond to medical treatment of ulcer, was found by intravenous pyelography to have distorted calices. He was entirely relieved of all his symptoms after the removal of a chronic hydronephrotic kidney. An example of the appendiceal type is a patient who was scheduled for an appendectomy. A rectal examination on the night preceding the date set for operation revealed a large distended seminal vesicle containing considerable amounts of pus. Massage cured the appendicitis. A patient treated for colitis for six months was found to have tuberculous seminal vesiculitis and tuberculosis of the left kidney, and later tuberculosis of an ankle. The diagnosis was made originally by finding tubercle bacilli in a specimen of urine passed in the office and later in urine obtained by renal catheterization. In those patients in whom the pain of renal colic is limited to the right hypochondriac and lumbar regions, biliary colic can be easily suspected. The shadow of the calculus may be found within the shadow of the gallbladder. Repeating the examination with the patient in an oblique position will reveal the presence of the calculus in the kidney. I believe, as the authors have shown, that the common innervation of the upper gastro-intestinal tract, the kidney and the upper part of the ureter through the celiac plexus by way of the preganglionic fibers from the lower dorsal spine and of the colon and rectum and the lower urinary tract through the sacral plexus will explain the causation of similar symptoms in both groups of cases.

DR. ANTON W. OELGOETZ, Columbus, Ohio. Four years ago I developed an infection which subsequently proved to be duplicated kidneys on the left side, with infection of one. Both kidneys on the left were removed. About a year later I developed a dull, boring, constant pain over McBurney's point. After a thorough search I was advised to have the appendix removed. As time went on I noticed the urinary stream

gradually becoming smaller. Finally some one passed a catheter and found a stricture of the urethra. It was evidently just a mucous affair, which acted more as a valve because the catheter passed through very easily. My symptoms abated immediately. Since then about every three or four months I have had a return of my trouble. We get out the wax catheters, pass a number 18 just once, and that cures my appendicitis.

DR. SIDNEY A. PORTIS, Chicago. Many clinical conditions have been omitted in the presentation of this subject. These omissions will be found in the complete publication of this paper. We particularly left out acute manifestations associated with fever, feeling that they did not belong to those chronic disorders for which gastro-enterologists are consulted and the clinical picture of which is so evident that the diagnosis should not be confusing. However, I am happy that Dr. McKenna reemphasized seminal vesicular disease with gastro-intestinal manifestations and reported improvement after adequate therapy. We have seen several of these cases and their clinical summary will be found in the paper. I am happy that Dr. Friedenwald emphasized the important symptom complex of hypertrophied prostate, particularly the fact that he feels that gastro-intestinal examinations are not complete without a rectal examination of the prostate and its surrounding tissues. I feel that the most important phase of this contribution is the emphasis on the frequency of urethral strictures in the female. This manifestation, so frequently overlooked and yet so easily found, should make one urologically minded. I am sure that many gastro-enterologists, as well as we have overlooked this condition in the past, and that they would be amazed at the marked improvement in the gastro-intestinal symptoms of these patients following the simple dilation of a strictured urethra.

TWO CARDIAC COMPRESSION TRIADS

CLAUDE S. BECK, MD

CLEVELAND

Lesions of the pericardium are generally difficult problems in diagnosis. Auenbrugger, Corvisart and Laënnec early recognized these difficulties. Osler not infrequently lamented his failure to recognize a lesion of the pericardium and it would seem that these problems in diagnosis still exist. The chief reason for failure in the diagnosis of pericardial lesions is the fact that the physiologic concept of acute and chronic compression of the heart has not found the place in applied medicine that it deserves. Clinically, almost all of the intrapericardial lesions express themselves, if they express themselves at all, by producing either acute or chronic compression of the heart. Some lesions of the pericardium are entirely silent; they produce no clinical signs whatever and clinical recognition of these silent lesions is not to be expected.¹ However, the important group of lesions—important because treatment is effective—produces either acute or chronic compression of the heart. In this respect the intrapericardial lesion producing compression of the heart is exactly similar to the intracranial lesion producing either acute or chronic pressure on the brain. The intrapericardial lesion, like the intracranial lesion, produces clear and distinctive earmarks for recognition. In the case of the heart the earmarks for both acute

¹ From the Department of Surgery of the Western Reserve University School of Medicine and the Lakeside Hospital.

In this group of silent lesions are the cases of adhesions between the normal parietal pericardium and the heart. Intrapericardial adhesions, per se, do not disturb the circulation. The circulation is disturbed if the parietal pericardium is thickened by the formation of scar tissue but the presence or absence of adhesions in this condition is entirely incidental. The thickened parietal pericardium produces chronic compression of the heart. Extrapericardial adhesions, per se, do not disturb the circulation and these also are silent lesions. However, extrapericardial and intrapericardial adhesions combined are not silent. In this condition the work load of the heart is increased and hypertrophy takes place.

and chronic compression can be reduced to three essential components. These two triads for cardiac compression are presented because I believe they not only will be useful in diagnosis but also will focus attention on the mechanical and surgical aspects of these lesions, placing the treatment on a more rational basis.

Fig 1—Cardiac compression triads. For comparison normal (fig 1), acute (fig 2) and chronic (fig 3). The acute compression is produced by fluid in the pericardial cavity. Note collapse of venous gateway and distention of veins outside the pericardium. The ventricles are shrunken and the heart per se is smaller than normal. The parietal pericardium has not had time to dilate nor has there been sufficient time for the liver to enlarge and for ascites to form. In the illustration for chronic compression of the heart the compression is produced by scar tissue. The heart is a small shrunken organ in contradistinction to cardiac dilatation. The veins dilate in response to the high venous pressure. The liver and spleen enlarge and ascites develops.

ACUTE CARDIAC COMPRESSION TRIAD

The acute cardiac compression triad (fig 1) consists of (1) a falling arterial pressure, (2) a rising venous pressure and (3) a small quiet heart. All other clinical manifestations of acute compression are secondary to this triad. The great venous gateway to the heart (the intrapericardial segments of the venae cavae and the right auricle) is partially or completely collapsed. The ventricles are also smaller than normal. The heart, being partially collapsed, is able to make only a feeble excursion and there is no visible or palpable precordial pulsation. This restricted pulsation of the heart can be seen by fluoroscopic examination, but the condition of the patient is usually so critical that this examination cannot be carried out. If the compression is due to intrapericardial hemorrhage and develops acutely (within several hours), as little as 200 cc of blood may be fatal. This collection of blood will produce a slight increase in the size of the cardiopericardial silhouette, but in acute compression the increase in size is frequently not demonstrable. There are no murmurs. The cardiac sounds are distant and muffled. A compression force of about 16 cm of water acutely applied to the heart is fatal. The venous pressure rises in a manner parallel to the rise in the intrapericardial pressure. The tension in the venous system is an exact measurement of the abnormal tension exerted on the heart. In this respect the venous system may be considered as a physiologic tambour that can record compression forces exerted on the great venous gateway of the heart. As the amount of blood enter-

ing the heart is reduced because of the compression of the heart and the venous gateway, the amount of blood expelled by the heart is reduced by an equal amount. The failure of the arterial circulation produces anxiety, restlessness, pallor, cold moist skin, a weak or imperceptible pulse and finally unconsciousness. These are secondary manifestations to failure of the arterial circulation. The differentiation between acute cardiac compression and acute cardiac dilatation need not be discussed.

The most common cause of acute cardiac compression is intrapericardial hemorrhage. The most common causes of intrapericardial hemorrhage are penetrating wounds of the heart, rupture of a myocardial infarct, rupture of a cardiac contusion, rupture of the auricle, rupture of a coronary or aortic aneurysm and rupture of the base of a sclerotic aorta. Hemorrhage occurs also from neoplasms growing within the pericardium. It develops in scurvy, in tuberculosis of the pericardium and in purpura. Dr Robert Dinsmore observed the development of the acute compression syndrome from mediastinal hemorrhage following the removal of a substernal goiter. Acute compression develops also when fluid other than blood forms rapidly in the pericardial cavity. The fluid may be sterile or infected. Acute cardiac compression may be produced also by gas pressure. The gas may arise from the lung (pressure pneumothorax, valvular pneumothorax) from the outside air or from a gas producing infection.

CHRONIC CARDIAC COMPRESSION TRIAD

The chronic cardiac compression triad (fig 1) consists of (1) a high venous pressure, (2) ascites and (3) a small quiet heart. All other clinical manifestations of chronic compression are secondary to this

Fig 2—Acute cardiac compression triad

triad. A much greater pressure on the heart and also on the great venous gateway to the heart can be tolerated if it develops slowly than if it develops rapidly. The intrapericardial pressure may rise to 38 cm of water. Accordingly, the venous pressure rises an equal amount. The walls of the veins stretch in response to this pressure and the veins stand out like goose quills. Likewise the liver and spleen enlarge in response

to the high venous pressure. These organs sometimes become covered by a layer of fibrin and fibrous tissue. This icy coating is not produced by infection, as was formerly believed. Venous stasis without infection can produce it. The ascites may be marked and may be the most conspicuous feature of chronic cardiac compression. The heart is quiet, showing little if any precordial activity. The reduction in diastolic-systolic excursion of the heart is best demonstrated by fluoroscopic examination. There are no murmurs. The sounds are distant and faint. The heart itself is smaller than normal, but one must not confuse the cardiac silhouette with the cardiopericardial silhouette. If the heart is compressed by fluid over a long period of time the pericardium stretches and the cardiopericardial silhouette is enormously enlarged but the heart per se is small and shrunken. A compressed heart cannot hypertrophy nor can it dilate.

Fig. 3—Chronic cardiac compression triad

The various lesions producing chronic cardiac compression have been presented in a previous publication.

TREATMENT

Cardiac compression should be regarded as diametrically opposite to cardiac dilatation. Not only are the triads of acute and chronic compression useful in diagnosis but, emphasizing as they do the mechanical aspects of two large groups of disorders, they should be useful in determining the nature of the treatment that should be given. The treatment of such mechanical disturbances obviously is surgical. Many of these compression syndromes, like those produced by stab wounds of the heart, tumors, scar, effusion, abscess or generalized pericardial infection, are recognized as surgical lesions. The question arises as to whether or not some of the lesions in the nonsurgical group can be placed in the surgical group. Perhaps some of the cases of spontaneous rupture of ventricles and auricles could be saved by operation. In a study of cardiac contusions, Dr. Ernest Bright and I² found that 20

per cent of those that went on to rupture seemed to be amenable to surgical repair, whereas operation was not carried out in a single case. The time is probably close at hand when the patient with a myocardial infarct or a myocardial contusion will be closely observed for the development of cardiac rupture, just as a patient with typhoid is watched for perforation of the bowel. Should rupture occur, the attempt to suture the bleeding point would be carried out immediately. Perhaps the time is not far distant when a prophylactic operation will be carried out for the purpose of strengthening the ventricle or the auricle so that the strain of intracardiac pressure can be tolerated. This could be done by placing a graft of pericardium over the weakened area in the heart. Undoubtedly the cases of acute and chronic compression of the heart offer opportunities for surgical intervention, and diagnosis is imperative. When the diagnosis is in doubt, exploratory pericardiotomy should be regarded as a justifiable procedure.

IS NEPHRECTOMY ALWAYS INDICATED FOLLOWING A DIAGNOSIS OF UNILATERAL RENAL TUBERCULOSIS?

STANLEY R. WOODRUFF, MD

JERSEY CITY, N. J.

AND

HERMON C. BUMPUS, JR., MD

PASADENA, CALIF.

The possibility that renal tuberculosis, once it has reached the point at which diagnosis is beyond question, ever heals has received considerable discussion during the last fifteen years. In 1920 Chute¹ reviewed three cases that occurred in his practice, he considered that there were indications in occasional cases that tuberculous processes of the kidney healed. He pointed out how such a belief is necessary if one is to accept the hypothesis of the hematogenous route of the infection. He says:

I believe we must assume that tubercle bacilli are brought in approximately equal numbers to both kidneys, that small cortical tuberculous infections are common and that far from going on to complete destruction of every kidney that is infected they are probably promptly stamped out in the greater majority of instances. The generous blood supply of the kidney allows it to overcome perhaps the greater number of infections while yet they are incipient.

After most careful experimental study, Lieberthal and von Huth² confirmed this observation and in the summary of their work state:

The kidney has a peculiar immunity to hematogenous infection with tubercle bacilli because of its copious blood supply and the comparatively large caliber of its blood vessels. Tubercle bacilli which are circulating in the blood tend to pass through the circulation of the kidney to lodge in other organs. Infection of the kidney occurs only if local disturbances in the circulation or the presence of the tubercle bacilli in large masses which cause embolism (suspended in fat droplets, adherent to debris or agglutinated masses of bacilli) allow the organism to lodge in the renal tissue.

If such emboli do become lodged, the work of Medlar³ would indicate that even then healing may occur if the original infection is not too extensive, a finding that has abundant clinical and experimental proof in a study by Harris⁴ of forty-three adults and sixty-seven children having tuberculous lesions outside the urinary tract. In 37 per cent of the adults and in 13.8 per cent of the children a tuberculous bacilluria occurred, and yet in the majority of cases there were no urinary symptoms. Harris was interested to see whether he could demonstrate that any of the unexpected incidences of symptomless tuberculous bacilluria were of the secretory type. He collected urine daily for ten days from three patients who were free of symptoms referable to the urinary tract but who had tuberculosis elsewhere. He wrote:

Each of these daily specimens produced tuberculosis when inoculated into guinea-pigs. In other words tubercle bacilli were present in the urine every day though the patients were free from symptoms. Were their presence due to excretion from the blood stream by the kidney an equally constant tuberculous septicaemia must have been present. A tuberculous septicaemia so constant and severe could hardly exist without the occurrence of military tuberculosis. None of the patients had at that time nor have they at the present any evidence of military tuberculosis. Blood cultures taken during the periods when urine was collected were free of tubercle bacilli. It seems certain, therefore, that the tubercle bacilli came from foci of renal tuberculosis.

In the majority of his cases, as stated urinary symptoms were not present. The frequency with which urinary tuberculosis occurs without symptoms is not generally appreciated. In reviewing 345 cases in which stained smears of urine contained acid-fast bacilli at the Mayo Clinic, one of us (Bumpus) working with Thompson⁵ found that twenty-eight patients (8 per cent) had no complaint referable to the urinary tract, from twenty-three of these patients tuberculous kidneys were removed. The other five also had renal tuberculosis but operation was thought inadvisable.

Bugbee,⁶ in reporting similar cases, has observed that "they lead one to believe that tuberculosis of the kidney probably exists much more frequently than is generally conceded, that a correct diagnosis of this type of case is often overlooked and that such a low grade tuberculous renal infection is self limiting in some cases."

Since a goodly proportion of Harris's patients without symptoms, but with bacilli of tuberculosis in the urine, ultimately became free of the organisms, as indicated both by examination of the stained smears and by the results of inoculation of guinea-pigs, it is not strange that in his conclusions he stated that "the initial renal lesions frequently heal, less frequently they steadily progress to complete destruction of the kidney and death of the patient."

In such symptomless cases, once the diagnosis of renal tuberculosis is made, the question arises as to the justification of nephrectomy. Henline⁷ answers this by stating which tubercle bacilli have been repeatedly recovered. "We believe that the removal of a kidney from

without other clinical evidence is an error of judgment," and he goes on to say that "until further convincing proof to the contrary is forthcoming we feel that some types of tuberculosis of the kidney will heal under certain circumstances." Braasch⁸ in a recent article observes that "the possibility of spontaneous recovery from renal tuberculosis must be recognized," while Thomas and Kinsella⁹ conclude an article on the subject by stating, "We cannot understand why tubercle bacilli behave differently in the kidney than in other tissue in that a renal lesion is not supposed to heal."

With such an apparent unity of belief relative to the possibility of renal tuberculosis becoming arrested, the question naturally presents itself: When is nephrectomy indicated? Certainly the keynote of whatever form of treatment is adopted must place emphasis on the fact that there should be no hurry about operative removal of a tuberculous kidney. It is never an emergency procedure, and there can be no excuse for neglecting the most painstaking examination to be certain that the remaining kidney is not involved. For if one accepts the hypothesis that renal tuberculosis in its pre-clinical stage is frequently bilateral, then the earlier one is able to discover its presence in one kidney the more chance there will be for it to be present in the opposite kidney, although undiagnosed. Certainly to perform a nephrectomy on a kidney from which the only evidence of tuberculous infection is the presence of organisms with possibly a few red blood cells and an occasional leukocyte and a few months later have the disease appear in the remaining kidney is as Henline has stated, poor judgment. It would certainly seem probable, with the increase in accuracy of diagnosis and the frequent discovery of the disease in symptomless cases, that this unfortunate outcome should be assiduously avoided.

If one could follow all the patients with renal tuberculosis for a certain length of time and particularly those in whom a proper hygienic regimen could be established, the incidence of healed lesions in the kidneys would probably be somewhat astonishing. We believe that the process of prolonged watchful waiting should however be insisted on in behalf of those patients in the adolescent period, as it has been agreed that younger patients are more prone to bilateral involvement than those of more advanced age and that nephrectomy should be performed only when definite cavitation exists. We believe that the coexistence of genital and renal tuberculosis gives preference to the former when operative procedure is indicated.

We have found that the result of the renal functional test is a most excellent guide in determining the time for operation. If this remains normal, or nearly so the disease has probably not advanced to any great degree, but a marked decrease in the amount of dye excretion, which can be demonstrated by the intravenous urogram as well as by the color dyes, would appear to show the necessity of surgical intervention.

There is little danger of the infection of one kidney by the other except through a deposit of the tubercle bacilli into the blood stream. Lymphatic connection between the two is not constant, and since the lymphatics of the kidney are practically all of the efferent type, such a contingency may usually be dismissed.

The clinical experience of finding in the majority of cases far advanced renal tuberculosis in the removed kidney, while the disease is absent in the remaining kidney, would indicate that not until late in the disease does the infection again become bilateral.

If there is vesical irritation or other evidence of beginning tuberculous cystitis, the question of the advisability of nephrectomy no longer exists. It is mandatory and it seems almost superfluous to add that, in cases in which the disease has advanced sufficiently to show unmistakable roentgenographic changes in the pyelogram, no question of the desirability of nephrectomy can be entertained.

The case, however, that gives questionable roentgenographic evidence of the disease and in which the tuberculous infection has caused so little damage as to produce but a few pus cells in the urine together with the organisms seems to us to deserve sanatorium care and observation rather than immediate nephrectomy.

This advice was given to such a patient when first seen by one of us (Bumpus) at the Mayo Clinic.

CASE 1—A man, aged 26, seen in October 1926, had been married six weeks before, shortly after which he noted an enlargement of the left testicle followed in a week or two by a smaller swelling of the right. At first the enlargements were associated with considerable pain, but during the next three weeks this had subsided, although the swellings had increased. His general examination was negative except for an acute vesiculitis, prostatitis and bilateral epididymitis. The left epididymis, being fluctuant, was operated on and drained.

He was seen next two months later when a cystoscopic examination showed normal renal function from both kidneys, as determined by a phenolsulphonphthalein test. The urine from the right kidney was normal, while that from the left showed an occasional pus cell. A diagnosis of bilateral tuberculous epididymitis and prostatitis was made and guinea-pigs were inoculated with urine from both kidneys. The test with the urine from the right kidney was negative and the one with the urine from the left was a failure. The patient was placed on heliotherapy with marked improvement. Jan 16, 1927, after a month's interval, cystoscopy was again done and this time the stained specimen of urine from the left kidney showed acid-fast organisms to be present. The right kidney urine was normal. The patient being dissatisfied with his progress, and at his urgent solicitation a bilateral epididymectomy was done February 18, and the diagnosis of tuberculous epididymitis was confirmed. There was no involvement of either testicle.

He was seen again in May 1927, and stated that a sinus had persisted on the left side following epididymectomy and that recently one had developed on the right side. Cystoscopic examination showed the renal function to be unchanged. The urine from the right kidney was normal, that from the left had an occasional pus cell. Two guinea-pigs were inoculated with urine from each kidney, those inoculated with urine from the left were failures, one of those inoculated with urine from the right kidney gave positive results and the other negative. A left pyelogram made at this time suggested evidence of cortical necrosis of the middle calyx.

In July, approximately a month later, cystoscopic examination was repeated and a right pyelogram was made because of the finding of a positive reaction at the previous examination. The pyelogram, although blurred, seemed normal. Pigs were again inoculated with urine from each kidney, those inoculated with urine from the right kidney gave negative results and both pigs inoculated with urine from the left kidney gave positive results. Seven weeks later two more pigs were inoculated with urine from the left side, the test in one pig was a failure and in the other gave positive results.

The patient was not seen again for three years, during which time he spent a considerable period in Arizona under

heliotherapy. When examined in July 1930, six pus cells to the field were found in the urine from the left kidney and stained smears showed acid-fast organisms, guinea-pigs inoculated with the urine were positive. A pyelogram of the left kidney showed the calices normal with the exception of one of the minor upper calices, which appeared to be missing. The pelvis was normal and there was no dilatation of the ureter.

The pyelogram on the right side was negative, the urine was normal, and the two guinea-pigs inoculated with urine from this side gave negative results. The bladder urine contained tubercle bacilli.

His next examination was made nearly four years later Jan 15, 1934. He had no urinary complaints and his general examination was negative, although a roentgenogram of the chest showed a healed lesion in the left apex. The one taken at his first visit was negative. The bladder urine contained only an occasional pus cell and was negative for tubercle bacilli. The bladder was entirely normal on cystoscopic examination. The urine from the right kidney contained an occasional pus cell and that from the left three in the high power field. Cultures of both proved sterile and stains were negative. Guinea-pigs inoculated with urine from the left kidney on January 22 were examined on February 26 and both gave positive reactions for tuberculosis, those inoculated with urine from the right kidney gave negative reactions.

The left pyelogram showed a normal pelvis but still some apparent abbreviation of the upper minor calyx.

The action of three patients observed by one of us (Woodruff) is interesting.

CASE 2—A woman, aged 32, complained on admission of severe hematuria of three weeks' duration. The appearance of the blood was sudden, and the amount has been about the same since the beginning. There were no premonitory symptoms and no particular frequency except since the appearance of the hematuria. Cystoscopic examination revealed blood coming from the left ureteral orifice. A very decided stricture was found in the left ureter about 5 cm beyond its orifice that resisted catheterization. With the aid of the terminal eye catheter, a successful ureteropyelogram was accomplished. The latter revealed no particular alteration in the pelvic outline except a slight fuzziness in the superior calyx. Following the pyelogram the hematuria immediately ceased, and the subsequent cystoscopy showed an equal and normal function from each kidney. The tubercle bacillus was demonstrated in the bladder urine. The history of this patient repeated itself yearly over a period of nearly five years. After each cystoscopy and pyelogram the hematuria would immediately cease and not appear again until the lapse of from six to eight months. In the meantime, the stricture of the ureter had been successfully dilated and at each cystoscopy the renal functional test appeared normal, the pyelogram showing the same fuzzy appearance in the upper portion of the superior calyx. The tubercle bacillus was demonstrated in the urine from the left kidney at each examination. After four and three-fourth years of this type of observation, the patient appeared with a hematuria after a lapse of six months. The pyelogram still showed no difference in appearance from the one taken at the beginning, but the functional test was now grade 1 instead of grade 4, as formerly. The patient also stated that she has lost some weight. Nephrectomy was advised at this time but was refused. Four months later the patient returned, but without hematuria, and consented to an operation because she felt herself that she was going downhill. Removal of the kidney revealed a typical tuberculous infection in its upper pole. There were, however, no abscess cavities of any demonstrable size. The patient is alive and apparently well at this time, which is six years after the operation.

CASE 3—A man, aged 34, presented a most desperate tuberculous condition. Examination revealed evident tuberculosis of the left epididymis, the right epididymis and testicle and a frank cavernous pyonephrosis of the right kidney. There are many tubercular organisms in the urine, these organisms coming mostly from the right kidney. There are a few organisms demonstrated in the urine from the left kidney. The

right kidney was evidently practically destroyed by caseo-cavernous infiltration of its substance. This patient urged that heroic measures be taken in an endeavor to effect a cure, and, rather against the author's will, a right nephrectomy, a right epididymo orchidectomy, and a left epididymectomy were performed. The patient was sent to the Loomis Sanitarium for treatment. After a stormy year there he purchased a house in Liberty and has lived there ever since. He has made several visits for observation during the past ten years, and in the last six of these no tubercle bacilli have been found in the urine.

CASE 4—A woman a nurse on whom bilateral renal tuberculosis had been clearly diagnosed, was given sanatorium treatment for one year, when it was found necessary to remove one kidney because of its evident destruction. Subsequently she was given sanatorium and rest treatment for a period of two years. At the end of that time no tubercle bacilli could be demonstrated in the urine. Four years after this she was found to have tuberculosis of the lumbar spine and an operation was performed a bone from her shin being transplanted to the diseased portion. This was followed by recovery and at this time, which is ten years after the nephrectomy, she is apparently well, and there are no tubercle bacilli in the urine.

Droegemueller¹⁰ has reported his observations on a tuberculous kidney in which the disease was so early that its only clinical manifestation was the appearance of tuberculosis in guinea-pigs after inoculation with urine from the kidney. He discovered practically no evidence of healing in the pelvic mucosa, while in the parenchymatous portion of the kidney signs that he interpreted as reparative processes were frequent. In conclusion he states

In considering healing of renal tuberculosis a distinction should be made between lesions involving the pelvis or in communication with the pelvis and circumscribed parenchymal lesions not in communication with the pelvis. Circumscribed tuberculous parenchymal lesions not involving the pelvis may heal at times. It is questionable whether true healing ever occurs in lesions that involve the pelvis.

In contrast to Droegemueller's case, case 1 at no time showed any evidence of pelvic or ureteral involvement. Advice against nephrectomy until evidence of a more extensive lesion in the kidney became manifest seemed justified. Had the ureter or pelvis given evidence of involvement by inflammatory dilatation a nephrectomy would have been urged. From a clinical standpoint, the disease seems arrested, only time of course can prove it permanently healed. In similar cases the keeping of the patient under observation rather than urging immediate nephrectomy would seem indicated, for every physician has observed how the clinical manifestation of diseases are undoubtedly changing. Glandular tuberculosis, common in our youth, is rarely seen today. The resistance of renal tissue to the tuberculosis bacilli may be undergoing a change, certainly its reaction in various parts of this continent appears different. For in the Northwest one sees many cases of calcification in the involved areas, not alone in the late cases but occasionally so early as to make the differential diagnosis from calculus difficult. Yet, in the Eastern clinics, calcified tuberculous kidneys are rarely seen, while in the Southern sections of the country the incidence of the disease appears so slow that at the last meeting of the Pan-American Medical Association held in Dallas the Southern urologists present all attested their surprise at the amount of interest manifested in the North about a pathologic process which they encountered so seldom.

SUMMARY

We believe there is sufficient laboratory evidence that tuberculous infection of the kidney actually heals. We believe there is great clinical evidence of this. Neither of these facts, however, prohibits reinfection.

We believe in adequate hygienic treatment of renal tuberculosis in its early stage, preferably in a sanatorium.

We believe that nephrectomy should be performed only when evidence of extension of the disease exists, when caseo-cavernous conditions can be demonstrated, or when the renal functional test has become markedly diminished.

16 Enos Place—1160 South Orange Grove Avenue

ABSTRACT OF DISCUSSION

DR R. M. LeCOMTE, Washington D. C. A clear distinction should be made between healing in renal tuberculosis and cure of the disease in the entire organ. Some evidence of healing may be found in practically every tuberculous kidney, but the occurrence of a complete cure may well be questioned. Renal tuberculosis pathologically, may mean anything from a minute solitary tubercle to an extensive process that has destroyed the whole parenchyma of the organ. In its surgical form it consists of an ulcerating or caseating lesion, characterized clinically by the presence of grouped pus and clumped bacilli in the urine and by evidence of destruction of the parenchyma, shown either by diminished function or by characteristic pyelographic changes in the suspected kidney. Unfortunately, not all the stages of this pathologic process are distinguishable clinically and there are certain errors necessarily associated with the manipulations required to make a bacteriologic diagnosis of the disease. These are soiling of the ureteral catheter specimens by the bladder contents, either by material carried up on the catheter or from an unsuspected vesico-ureteral reflux or by tuberculosis of the lower segment of a ureter the kidney of which is quite normal. Each of these possible errors makes it more likely that diagnosis of tuberculosis will be made in a normal kidney than that it will be missed in a diseased one. To establish a cure in a surgical form, it would be necessary to show that the previously diseased kidney was capable of secreting a urine free from pus and bacilli and was negative both on roentgen study and on urography. I do not consider the pathologic studies of Dr. Medlar absolutely conclusive, because they were done on kidneys of people who died of pulmonary tuberculosis and the lesions studied differ materially from those encountered in the living operable subject. None of the clinical references describe in sufficient detail a case that would answer the criteria of cure just noted, and all the apparent cures might easily be explained on the basis of more or less prolonged remissions or possible technical errors in the diagnosis. As Dr. Thomas's work has been reported, it can be subjected to criticism, for no matter how skilful and careful a cystoscopist may be, he is in constant danger of having the ureteral catheter soiled in one way or another. There is considerable question in my mind as to whether Dr. Bumpus's patient might not have been benefited more by a left nephrectomy in 1927 than by the years of general treatment that he received, and whether he might not be benefited by it now or eventually come to it. I believe that Dr. Woodruff cured his three cases by removing a unilateral tuberculous kidney, although the clinical examination gave rather confusing data as to the freedom from infection of the remaining kidney in the second and third cases. I rather deplore the tendency to get away from surgery in the early unilateral cases, because it is in them that the best results are obtained.

DR J. C. PENNINGTON, Nashville, Tenn. I have been urologist to the Davidson County Tuberculosis Hospital for eight years. It has a capacity of 300 beds and is always full. The interns have many times demonstrated tubercle bacilli in the urine of patients free from urinary symptoms. We have had only one case in the eight years which required surgery for tuberculosis of any part of the genito-urinary tract. This patient was a man who had tuberculosis of each epididymis.

¹⁰ Droegemueller E. H. Renal Tuberculosis. A Detailed Study Made Early in the Disease, S. Clin. North America 13: 1007-1016 (Aug.) 1933.

and each seminal vesicle. It has been remarkable how few tuberculous lesions of the genito-urinary tract were found in cases of pulmonary tuberculosis. Whether or not the finding of bacilli in symptomless cases means that there is active tuberculosis in the urinary tract, I am unable to say. It has been our policy to leave such cases alone and let them continue with their treatment of pulmonary tuberculosis.

DR. HUGH H. YOUNG, Baltimore. This is a subject of such great importance that we should consider it thoroughly before giving forth to the medical world that the Section on Urology even considers the advisability of not carrying out nephrectomy in the presence of an early tuberculous lesion on one side. The diagnosis is difficult. Tubercle bacilli are not always to be found in the urine nor do guinea-pigs always die from urine injections from a definite renal tuberculosis. I remember the case of a young man in whom tubercle bacilli were found elsewhere in the urine from the right kidney. When seen by me and my associates two months later the urine was absolutely negative. Numerous studies and animal inoculations showed no tubercle bacilli and ureteral catheterization was also negative. Inoculated guinea-pigs were killed from two to three months later and were negative. About six months later the patient came down with a right epididymitis, the right seminal vesicle was involved, and the diagnosis of tuberculosis was positive. I carried out right epididymectomy, vasectomy and seminal vesiculectomy but as the prostate seemed not to be involved and the right epididymis and vesicle appeared normal, I did not remove them. Seven years later the patient returned with cloudy urine and tubercle bacilli were obtained from the right kidney. Nephrectomy and partial ureterectomy were performed. For five years thereafter the patient was apparently well. The urine was normal. In February 1926 (twelve years after the first partial seminal tract operation) the patient returned with tuberculosis of the right epididymis. It was not possible to recognize tuberculosis of the prostate or remaining vesicle. He lived in Colorado and insisted on taking heliotherapy. Five years later he died of pulmonary tuberculosis complicated by pneumonia, eighteen years after the initial lesion in the kidney had been discovered. This case demonstrates conclusively that it is often difficult to find tubercle bacilli in an early renal lesion. (After eight years the tuberculous area in the kidney removed by me was still small.) This case also shows the importance of removing both vesicles both vasa deferentia and epididymides and also the lateral lobes of the prostate when the radical operation is carried out. The serious error was in failing to recognize the very early tuberculosis in the right kidney. Now intravenous and retrograde pyelography would have prevented such a mistake. The case is an argument against the nonoperative treatment of even slight renal tuberculosis. After a careful recent study of all our cases of tuberculosis of the genito-urinary tract I am absolutely convinced not only that early nephrectomy and partial ureterectomy are desirable but that wherever tuberculosis has involved an epididymis there is practically absolute certainty that the vasa, vesicles and prostate are also involved and that an early bilateral radical operation on the seminal tract is indicated as soon as the patient has recovered from the nephrectomy.

DR. H. C. BLUMPS, JR., Pasadena, Calif. Dr. Woodruff and I wished to emphasize the point that with the diagnosis of renal tuberculosis being made increasingly early one must be absolutely certain that only one kidney is infected. I have seen many nephrectomies performed when the microscopic study of the urine from the remaining kidney was negative only to have the guinea-pig reported positive a few weeks later. Such patients develop or had one better say continue with the infection in the only remaining kidney. That is why we asserted that nephrectomy for tuberculosis is never an emergency procedure. Dr. LeComte referred to the case I reported. A nephrectomy was done last week. The patient's urine was free from pus, he had no roentgenographic evidence of tuberculosis and was free from symptoms, and only the guinea-pigs were positive. After eight years the kidney showed as in Dr. Young's case, a very limited single lesion a few millimeters in diameter, a finding that further emphasizes I believe that nephrectomy for tuberculosis can safely await the most exacting examination. It is never an emergency procedure.

QUARTZ LIGHT THERAPY IN UROGENITAL TUBERCULOSIS

STANLEY L. WANG, MD

NEW YORK

Quartz light therapy has been included in the treatment of urogenital tuberculosis for the past eight years. It is not used alone but is a part of the general plan of treatment. The general plan is to remove the active lesions by surgery, so far as this may be done advantageously, and then to follow the surgery by a long course of after care. The after care, as is also the treatment of inoperable patients, is based on the traditional method of treating tuberculosis, namely, rest, fresh air and proper diet. To these are added other measures and procedures that have been found useful and that seem indicated in the various kinds of patients. Among the useful measures is quartz light therapy.

The air cooled mercury vapor quartz lamps of both the older and the newer types have been employed for the local irradiation of sinuses and for general irradiations over the regions of the kidneys and bladder. Formerly water cooled mercury vapor quartz lamps

TABLE 1—Irradiation of Wounds and Sinuses

	Number of Patients	Number of Months Treated with Quartz Lamps Before Healing	Average Months

were used to some extent for local treatment. More recently about a year and a half ago irradiation of the interior of the bladder of patients suffering from bladder tuberculosis was begun with a lamp that is somewhat of a variant from the usual mercury vapor quartz lamp.

The air cooled lamps have been very useful in the treatment of wounds and sinuses. Sinuses following the surgery of urogenital tuberculosis are of considerable importance for they occur in a more or less certain percentage of patients. The sinuses usually ensue within a few weeks after the operative treatment, when as a result of abscess formation the incision line breaks open partially or completely. When the entire incision or a large part is involved, a deep wound is formed, which discharges pus profusely. The postoperative recovery is delayed and there is a long period of inconvenience as the result of the frequent dressing of the wound. Previous to the advent of quartz light therapy postoperative sinuses particularly following nephrectomy for tuberculosis had a long standing reputation for persistence, and there were numerous reports that drainage often continued for three years and occasionally longer. Besides the patients with sinuses following surgery there were other patients with sinuses

from tuberculosis of the epididymides or testicles who were deemed inoperable or who refused operation

Table 1 gives the healing of the wounds and sinuses in postoperative and inoperable cases. The local treatment was irradiation with the air cooled mercury vapor quartz lamps and in a few instances it was alternated with heliotherapy. The treatments were given twice each week beginning with a one minute exposure at a distance of 20 inches from the wound. The time was gradually increased to seven minutes and the distance then slowly shortened to 15 inches. With the older lamps the treatments were begun at three minutes at a distance of 20 inches and gradually changed to ten minutes exposure at 8 inches. After these settings had been reached the treatments were continued until the wounds healed, with occasional variation according to the skin reactions. The progress seemed most satisfactory when there was no other treatment of the wound than cleansing the edges with dilute alcohol and applying the dry gauze dressings. There seemed to be slowness in the healing when there had been a long interval between the development of the sinus and the institution of the treatment, also when the patients did not come for treatment regularly. One in the series had nephrectomy at another hospital four years previously. The postoperative sinus that had persisted during the four years healed after a long course of the irradiations. Two others had retro-ureteral reflux of urine from the bladder into the postnephrectomy sinuses, but it seemed to cause no delay in the healing. In three, small sinuses developed in the post-nephrectomy scars several months after the first sinus healed, these soon closed however. In the cases of tuberculosis of the epididymides that were treated surgically, healing occurred on the average in about half the time (37 months) necessary for healing of the

in all inoperable and postoperative cases presenting tuberculosis of those organs. Cases of epididymal or testicular tuberculosis are treated in a like manner. The treatments are begun gradually and the lamps are brought closer, depending on the skin reactions. Short exposures of seven or eight minutes at from 12 to 15 inches have worked out well. The heat of the lamps seems to have a good influence. In table 2 are the results of treatment of 156 cases, which included this method of quartz light therapy.

TABLE 2—Results of Treatment that Included Quartz Light Therapy

	Apparently Cured	Im proved	Unim proved	Died	Total
Postnephrectomy	10	39	15	5	75
Inoperable renal		23	8	3	39

Posturethrotomy			2		2
Inoperable epididymitis	10		2		12
Inoperable orchitis	1				1
Totals	44	73	29	10	156

There is no way of appraising the value of the procedure. It is further made difficult by the fact that it is only one measure in a general regimen of care. The patients as a general rule, however, insist that it is of benefit. No harmful effects were noted, even though in some instances the irradiations were continued for as long as three or four years. The impression has been gained that this part of the regimen is worth while.

Irradiation of the interior of the bladder of patients with bladder tuberculosis has been carried on for more than a year and a half. It was begun soon after Caulk

Fig 1—Comparison of the two spectrums above quartz mercury arc spectrum Alpine Sun Lamp below high voltage mercury discharge spectrum

group in which operation was refused or which were deemed inoperable (71 months).

There were, in addition to the patients in table 1, one with a postnephrectomy sinus who discontinued treatment after a few months with her wound still draining. Five with postepididymectomy sinuses stopped their treatment after five, four, seventeen, twenty-four and twelve months. Two with postseminal vesiculectomy sinuses were unhealed after twelve and fourteen months. Two with renal tuberculosis had urethral sinuses following urethrotomy for stricture which were still draining after thirty and four months.

On the whole the results seem to indicate that the quartz lamps are of value in the treatment of wounds and sinuses in this class of case.

Irradiations with air cooled lamps over the regions of the kidneys and bladder are given twice each week

and Ewerhardt¹ reported the treatment of a case of bladder tuberculosis by intrabladder irradiation with a special quartz lamp arranged so as also to introduce air. The lamp I have used differs mechanically and in its emission from the air cooled mercury vapor quartz lamps. Mechanically it is of the high voltage discharge mercury vapor type and operates at a temperature sufficiently low that the heat of the electrode is barely felt on the skin or mucosa. The difference in the emission of the rays is clearly shown by the comparison of the two spectrums. The rays from the high voltage discharge mercury vapor lamp varies from the other in that they are more of a monochromatic nature since about 90 per cent are concentrated in the wavelength at 2537 angstrom units.

¹ Caulk J R and Ewerhardt F H. Direct Internal Irradiation of Ultrasound to the Bladder. Arch Phys Therap 13 325 327 (June) 1932.

The intrabladder applicator is of fused quartz built according to the design by Dr. Oswald S. Lowsley and myself. It is about the same shape as a Brown-Buerger cystoscope and approximately 24 French in diameter. There is an extra tube built into the fused quartz with an opening near the tip of the applicator and with an extension at the other end for the attachment of a rubber tube. The extra tube is for the purpose of catheterizing the bladder and after it is

Fig. 2—Appearance of applicator

emptied of urine air is insufflated with a syringe to distend the bladder slightly before irradiation. Following the treatment an instillation can be made through the tube if desired. The applicator with the exception of the part at the distal end, which protrudes into the bladder, is painted with a dark oak stain made with a cellulose base to screen the rays from the urethra. When urethral irradiation is desired, the stain is easily removed with amyl acetate and can be reapplied when needed.

The device has been found to be practical for irradiating the interior of the bladder. The applicator passes easily through the urethra into the bladder with little discomfort to the patient. The bladder is emptied of urine, slightly distended with air and irradiated, and the air is permitted to escape from the bladder at one operation and in a very short time.

TABLE 3—Results of Intrabladder Irradiations

	Improvement			Unimproved
	Marked	Moderate	Slight	
Postnephrectomy	2	2	6	4
Inoperable renal			1	
Total number of patients treated	15			

The intrabladder irradiations were given once each week. The time varied from five to twenty seconds, depending on the local reaction. Longer time and more frequent treatments seemed to be unsatisfactory. A small amount of liquid petrolatum, which permits the passage of the rays, was used on the tip of the applicator for lubrication. Although no mishap has yet occurred, it was thought best to insufflate only a little air, and an opportunity was given for it to pass out through the extra tube in the applicator after the treatment. The instrument was sterilized in the formaldehyde cabinet and when several patients were treated it was sterilized between applications by immersion of

the applicator in 1:1,000 mercuric oxycyanide solution for ten minutes.

Fifteen patients were treated as shown in table 3. The results were encouraging. This group presented a somewhat severe test, as all the patients had old bladder lesions that had not responded to other measures. Several had badly crippled bladder function due to extensive disease of the cystic wall, which had diminished the capacity and rendered the organ sensitive to small quantities of urine. The improvement, when it occurred, was evidenced by a lessening of the sensitivity and a decrease in the urinary frequency. Usually the intensity of the local symptoms was increased for from twelve to twenty-four hours following the treatment. One patient with a rather large ulcer showed a marked decrease in the size of the ulcer as seen through the cystoscope, and the urine became free from acid fast bacilli. Another became free from the bacilli, and the condition of the bladder interior seemed improved. One who was apparently much better also had a lessening of the number of bacilli in the urine. There was no improvement in symptoms or in the appearance of the bladder in four cases.

The treatments were tolerated remarkably well. No harmful effects were seen. While not all were benefited there was a sufficient number to warrant the belief that intrabladder therapy of this kind has a place as an adjunct or supplemental measure in the treatment of bladder tuberculosis. Perhaps patients with earlier and more favorable lesions would have improved results.

126 East Sixty-First Street

TUBERCULOSIS OF THE GENITAL TRACT

HUGH H. YOUNG, M.D.

BALTIMORE

The subject of tuberculosis of the seminal tract has for years been highly controversial. Some of the questions at issue have been: Which is the primary seat, the epididymis or the seminal vesicles? Does the pathologic process within the scrotum start in the globus major or the globus minor? Does it reach these through the blood stream, by the lymphatics or down the vas deferens? Has heliotherapy or hygiene any value? Is castration preferable to epididymectomy? Should operation be attempted if the bladder, kidneys or lungs are involved? Seminal vesiculectomy has hardly been mentioned.

In the literature one will find a great array of papers in which leading surgeons and urologists have expounded views at variance on the subject of genital tuberculosis. In my early days on the surgical staff of the Johns Hopkins Hospital, castration was the rule in genital tuberculosis. Later we employed the Bardenheuer operation of epididymectomy.

A little later von Bünner recommended that after isolation of the epididymis, in order to remove as much as possible of the tuberculous vas it should be forcibly divulsed by violent traction, which often brought considerable lengths of involved vas deferens from back of the bladder through the inguinal canal, but subperitoneal infection and miliary tuberculosis occasionally resulted. I then modified the procedure by dividing

From the James Buchanan Brady Urological Institute, Johns Hopkins Hospital.
Read before the Section on Urology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

the vas deferens below the external ring and then, by means of a clamp in the inguinal canal, brought it out through the skin of the groin, opposite the upper end of the inguinal canal, where free drainage could be obtained and the seminal vesicles be treated by intravasal injections.

In 1900, being convinced that seminal vesiculectomy was desirable in certain cases, I presented an extra-peritoneal, retrovesical suprapubic method of removing the seminal vesicles and epididymides. Although this technic was not difficult, the results were not good, because the drainage of the deep wound was unsatisfactory. Postoperative miliar tuberculous occurred. As the years went by I was impressed more and more with the fatalities that occurred with considerable frequency in cases of genital tuberculosis which had been treated only by epididymectomy or castration.

Having attacked the seminal vesicles in conjunction with the operation of perineal prostatectomy, I again resorted to seminal vesiculectomy through the perineum

in cases of tuberculosis.¹ Using a long prostatic tractor, which could be introduced through the urethra I had little difficulty in removing the seminal vesicles and involved portions of the lateral lobes of the prostate through the perineum, without opening the urinary tract and then at the same sitting, in removing the one or both epididymides and the entire vas deferens through an incision in the groin. This operation is sufficiently depicted in the accompanying illustrations.

After employing this technic for nine years I collected

Fig 1—The posterior layer of Denonvilliers' fascia has been pushed backward with the rectum exposing the anterior layer of Denonvilliers' fascia covering prostate and seminal vesicles. Y shaped incision through capsule is shown.

all cases of tuberculosis of the genito-urinary tract in which operation had been done in the general surgical wards and in the urologic department.² These studies proved to be of great interest. In the first place, it was shown quite conclusively that tuberculosis of the epididymis began more commonly in the globus minor than in the globus major, that it reached the epididymis probably through the lymphatics perhaps also by way of the vas deferens, but not often through the blood stream, that the testicle was rarely involved until late, and that castration was seldom necessary. This study showed also that in the majority of cases the seminal vesicles were involved or were surely the primary focus from which the tuberculosis spread to the epididymis in most instances, that from the seminal vesicles the kidney was not infrequently involved by

the retroperitoneal lymphatics, and that from the same source the bronchial glands and the lung itself sometimes were invaded. These statistics showed conclusively that Kocher's assertion was true that an operation on genital tuberculosis is indicated, even though the lungs are involved, that the more the external focus of disease can be removed, the better

Fig 2—Denonvilliers' fascia dissected up from the lateral lobes of the prostate and seminal vesicles.

chance there is for the arrest of the pulmonary involvement.

In the same paper I presented a complete report of fifteen cases in which my radical operation for tuberculosis of the seminal tract had been carried out. Among these, lung tuberculosis was present or suspected before operation in seven cases, and renal tuberculosis before operation in five, the operative mortality was 0. There was one death from lung tuberculosis

Fig 3—The left seminal vesicle has been freed after its pedicle has been clamped, ligated and divided. The vas divided high up is clamped and drawn downward. The right vesicle is freed and drawn down in the same way.

twelve months after operation, and one patient had not been heard from. An excellent result was obtained in thirteen cases.

This report showed very conclusively that the radical operation for tuberculosis of the seminal tract, combined (if necessary) with epididymectomy, with castration and sometimes with nephrectomy, which had been carried out in three cases, showed very much

¹ Young H H Surg. Gynec. & Obst. 28 608-615 (June) 1918
² Young H H The Radical Cure of Tuberculosis of the Seminal Tract Arch Surg. 4 334-419 (March) 1922

better results than had been obtained by the partial operations of epididymectomy and castration

Very conclusive proof of the inadequacy of epididymectomy is shown in a later study of cases³ of unilateral tuberculosis of the epididymis, without involvement of the kidneys, ureters or bladder, and is as follows

Resume of 38 cases of unilateral epididymectomy without urinary involvement. Dead, 11 cases 29 per cent. Of those alive, 5 have been followed less than 1 year. Well on last report, five years or more 6 cases, four years, 2 cases, three years, 1 case, two years, 2 cases one year, 2 cases, less than one year, 3 cases, total 16 or 42 per cent. Well over one year, 13, or 38 per cent. Improved 5, or 13 per cent. Not improved 6, or 16 per cent. Of the 16 cases classed as well, all but 5 required other operations after the primary epididy-

Fig 4—The seminal vesicles ampullae and lateral lobes of the prostate have been freed from the bladder and urethra which remain intact. The vasa deferentia are still held by clamps

mectomy viz. nephrectomy 4 epididymectomy on other side 7, radical operation seminal tract, 1. In 15 (40 per cent) we know that the opposite epididymis became involved subsequently

I have intentionally included the two previous sets of statistics to show how my early confidence in the radical treatment of genital tuberculosis has been confirmed by subsequent studies of cases. With the passage of time, and with successful results in cases far advanced or complicated with tuberculosis of the lungs or kidneys, or both I have made bold to extend the operation even to cases in which the prognosis was manifestly poor, with the hope that at least local relief and prolongation of life could be obtained. There are a number of such cases in the fifty I am now present-

ing. Among these tuberculosis of the lungs was definitely diagnosed by x-rays in twenty-seven cases, twelve as active and fifteen as inactive. Unilateral tuberculosis of the kidney was present in fourteen cases and bilateral involvement in one. Tuberculosis of the bones and joints was present in four. Epididymal involvement was present, unilateral in fourteen and bilateral in thirty-one cases. There were five cases in which there was no involvement of the epididymides. The prostate and vesicles were involved in all.

Before the radical operation was carried out, the following operations had been done: epididymectomy, unilateral in five and bilateral in one; drainage of the epididymis, five; castration, eleven; nephrectomy fourteen. There were other cases in which vesical tuberculosis was present and in some cases perivascular sinuses and fistulas or infections, which rendered the operation more difficult and hazardous.

The results obtained in these fifty cases are shown in the following summaries. There were four deaths in the hospital. In one of these there was a retrovesical abscess before operation and the patient died from tuberculous peritonitis. In the other three cases death resulted from complications of the lungs previously present. There were no operative deaths.

Dr Lloyd G. Lewis has made a very careful analytic study of these cases based on questionnaires, and has also personally examined a good many of the patients. He has been able to follow forty-one cases in which the radical operation has been performed. The results are as follows: Seven patients are living and well more than ten years after operation, and one patient died after seventeen years of pulmonary tuberculosis which was present before operation. There are seven patients who were operated on from five to eight years ago. Three of these are known to be free from tuberculosis, and four have been cured of genital involvement but still suffer from pulmonary lesions. Three patients died nine, eight and six years, respectively, after operation, two of pulmonary tuberculosis (which was present before operation) and one of diabetes. Nine patients have died of tuberculosis within two years after leaving the hospital: lungs, three; kidneys, one; meninges, one; miliary, three; undetermined, one. These patients had pulmonary tuberculosis as shown by roentgen examination before the radical operation was performed. Sixteen patients are living from one to seventeen years after operation. Of these, eight are free from tuberculosis and eight have signs of tuberculosis elsewhere: vesical tuberculosis, two; renal (bilateral), two; colon one; lungs, two; bones and joints one. All these complications were present on admission.

In determining the value of the radical operation in these cases, which have been tabulated and analyzed one must consider the conditions present on admission. As stated, tuberculosis of the lungs (active or arrested) was shown by the x-rays to be present in 50 per cent of the cases, unilateral involvement of the kidneys in fourteen cases and bilateral in one and tuberculosis of the bones and joints in four cases. It is therefore evident that many patients included in this series were poor operative risks. The fact, however, that twenty-seven of the forty-one patients are living and that sixteen of them are shown to be entirely free from tuberculosis and the others with only preexistent involvement in other organs, proves conclusively the value of the radical removal of the entire seminal tract involvement.

As an example of the possibilities of the operation, three cases are herewith cited in brief

N D, aged 29, admitted Oct 7, 1916, had had the right kidney and epididymis removed for tuberculosis seven years before. Examination showed involvement of the remaining epididymis, prostate and vesicles, but these were completely removed by the radical operation. Examination now (fourteen years later) shows him to be free from tuberculosis and well.

A O, aged 26, admitted Jan 26, 1924, had had a nephrectomy for tuberculosis performed five years before. Examination showed tuberculosis of the seminal vesicles, prostate, epididymides and bladder. Complete radical operation was carried out and the patient now reports (seven years later) that he is well.

A B, aged 43, admitted June 3, 1925, had had the left kidney removed three years previously on account of tuberculosis. Examination showed involvement of both epididymides, vasa and vesicles. Complete radical operation was carried out. Six years after operation the patient was free from tuberculosis but had diabetes and died of carbuncle.

In closing I can, with every assurance of accuracy, state that at the Brady Urological Institute the addition of seminal vesiculectomy to epididymectomy in cases of genital tuberculosis has given far better results than were ever obtained by simple epididymectomy, and that the radical operation in itself is accompanied by a minimum of danger, the fatalities having in all instances been of patients with severe complications.

CONCLUSIONS

A series of statistics have been presented which are in complete agreement as to the following facts concerning genital tuberculosis:
